Acknowledgements

The authors are grateful to the study respondents who shared their time and experience with us. Most importantly, we would like to thank GFATM for their generous funding. The contribution of reviewers particularly Dr. K. Zaman, epidemiologist and scientist, ICDDR,B and Dr. Marijke Becx-Bluemink, independent consultant to improve the intellectual content of the report is gratefully acknowledged. Finally, we would like to humble acknowledge the contribution of all the staff of BRAC Health, Nutrition and Population Programme, the study investigators, the editorial support received from Mr. Hasan Shareef Ahmed, Coordinator, Knowledge Management Unit, RED.

RED is supported by BRAC's core fund and funds from donor agencies, organizations and governments worldwide. Current donors of BRAC and RED include Aga Khan Foundation Canada, AusAID, Australian High Commission, Brigham Young University, Bill and Melinda Gates Foundation, BRAC University, NIKE Foundation, Campaign for Popular Education, Canadian International Development Agency, Charities Aid Foundation-America, Columbia University (USA), Conrad N Hilton Foundation, Danish International Development Agency, DEKA Emergence Energy (USA), Department for International Development (DFID) of UK, Embassy of Denmark, Embassy of Japan, European Commission, Fidelis France, GITAC Consult GmbH, The Global Fund, GTZ-Germany, Government of Bangladesh, The Hospital for Sick Children, ICDDR, B Centre for Health and Population Research, ICLARM/World Fish Centre, Institute of Development Studies (Sussex, UK), Inter-cooperation Bangladesh, International Committee of the Red Cross, Japan International Cooperation Agency, International Research and Exchange Board, The Johanriter, Land O Lakes (USA), Manusher Jonno Foundation, Micro-Nutrient Initiative, NORAD, NOVIB, OXFAM America, Plan Bangladesh, The Population Council (USA), RNE/DGIS, Embassy of the Kingdom of the Netherlands, Royal Norwegian Embassy, Scojo Foundation Incorporation, SIDA, Sight Savers, Stanford Medical School, Swiss Development Cooperation, ULG Northumbrain, UNICEF, United Way International, University of Calgary, University of Leeds, University of Manchester (UK), World Bank, World Food Programme, and World Health Organization.

Abstract

This study was conducted to explore the knowledge and perceptions of health workers and community people about tuberculosis in geographically inaccessible (hard-to-reach) tuberculosis (TB) programme areas of BRAC. The study also explored the healthseeking behaviour of TB suspects (having cough >3weeks) and challenges faced by the programme in this particular situation. This cross-sectional survey was conducted in 15 'hard-to-reach' upazilas (out of 30 such upazilas), and another 15 upazilas, adjacent to the above upazilas and selected randomly for comparison. The study included 338 health workers (Shasthya Shebika or SS), 3,600 community people, 1,800 TB suspects and 1,800 non-suspects. Two modules of questionnaires (structured and semistructured) were developed for the health workers and the community people. The study found that the misperception that TB is 'a disease of only male' was common among the health workers (44%) and community people (46-57%). Further, many of them misperceived the common ways of acquiring TB such as by sharing patients' utensils (46-49%), smoking (80-87%), and that TB could be prevented by avoiding smoking (58-63%). Almost half of the SSs (49%) could not recall at least four messages on TB that they learned from training. Many of the SSs confessed that they were not involved (64%) in delivering TB messages in the community, and a significant numbers of SS (41%) were not motivated to work in the TB control programme.

The community people lacked basic information on TB. Further, almost about half of the community people (41-47%) were afraid of TB in both the study areas, and a majority of community people (52-56%) reported that they wanted to stay away from the TB patients. The study further found that one-third did not take any treatment for their illness (median duration of illness being six weeks), and two-third did not undergo sputum test. The main sources of treatment of TB suspects were village doctors (26-35%) and attendants at drug shops (35-36%). The geographical distance, treatment non-compliance, and lack of trust in SSs' management were identified as the major constraints in hard-to-reach areas for implementing TB programme efficiently. The implications of these in management of TB control programme are discussed and recommendations are made.

Executive summary

Tuberculosis (TB) is a major public health problem in Bangladesh, which ranks 6th among the 22 'high TB burden' countries. The overall prevalence of new smear positive is estimated at 79.4 per 100,000 adult population. To combat the TB havocs, the government of Bangladesh (GoB), in partnership with different non-governmental organizations (NGO) including BRAC (one of the largest NGOs in the world), has been implementing a community-based TB control programme using the Directly Observed Treatment, Short-course (DOTS) strategy. At the core of the model is BRAC's female community health volunteers known as Shasthya Shebikas (SS). As frontline health workers, the SSs maintain a semi-active case finding strategy, and mobilize the community people during their routine home visits to search for TB suspects (person with prolonged cough for at least three weeks), and refer them to either BRAC union level sputum collection sub-centre or sub-district microscopy facilities, depending on the patients' convenience for sputum test. Identified TB patients visit the SS's home daily during the initial 2-3 months of treatment. Subsequently, patients collect medicines once a week from the SSs' homes, and the SSs ensure follow-up over the full 6-9 months course of treatment.

Currently BRAC is implementing the TB control programme in 293 sub-districts of 42 districts with technical support from the National TB Control Programme (NTP). Despite being successful in achieving a high rate of case detection and treatment completion, there are challenges as well. BRAC's TB control programme includes some areas which have poor communication, such as Char area (surrounded by water), hill tracts, and coastal areas. The programme refers to these areas as 'hard-to-reach' areas. There is paucity of information on the performance of the programme in these areas. So far, no independent evaluation has been conducted to explore how far the programme objectives have been achieved in terms of raising awareness among the health workers and community people about pulmonary TB (PTB), and changing health-seeking behaviour of the community people for appropriate and quick treatment. Misperceptions associated with TB, inadequate knowledge and poor health-seeking behaviour are often observed in high TB burden countries. These may act as important obstacles to service utilization and to successful control of TB.

This study explored the existing misperceptions, and the knowledge of health workers and community people regarding TB. In addition, the study explored the health-seeking behaviour of TB suspects, and challenges of the programme that impaired implementation of TB control efficiently. The findings would help further fine-tuning of the programme in terms of resource allocation, programme modifications, etc., and provide a benchmark for future impact assessment. More specifically, the study aimed to investigate:

- Misperceptions and knowledge of health workers and community people (TB suspects and non-suspects) about tuberculosis
- 2. Health-seeking behaviour of TB suspects
- 3. Challenges the TB control programme faces in hard-to-reach areas

Methods

This cross-sectional survey was conducted in 15 'hard-to-reach' upazilas (out of 30, defined by the programme) and another 15 upazilas (adjacent to the hard-to-reach

upazilas), selected randomly for comparison. The study respondents were general people or non-suspects (without clinical symptoms of TB, n=1,800), TB suspects (having cough ≥ 3 weeks, n=1,800), and the SS of the BRAC programme (n=338). Both structured and semi-structured questionnaires were used for data collection.

Key findings

| Domains | Key findings | Comments |
|--------------------|--|-------------------|
| Sociodemo | The study found that one-fifth of SS (19%) had no school | Table 4-5 |
| graphic | education. The average length of service of SS was around six | |
| variables of SSs | years. Many SSs (75%) frequently consulted TB suspects during the last month, and treated TB patients (88%) using DOTS during | |
| 003 | the last year. Interestingly, one-fourth of SSs (24%) did not know | |
| | or did not have knowledge about the correct meaning of DOTS. | |
| Challenges | Almost half of SSs (47%) could not remember more than three | Table 6 |
| for the | basic TB messages for the community which they learned from | and 10 |
| programme | training. More than half of SSs (60%) faced difficulties in moving | |
| | around in the hard-to-reach areas, and 41% lacked the motivation | |
| | to work in the TB programme. Further, poverty of health workers | |
| Misposopti | (28%) and lack of trust in SSs' management (20%) were noted. | Table 5 |
| Mispercepti on and | Misperception such as TB is 'a disease of only male' was common | Table 5 and 12 |
| knowledge | among health workers (45%) and community people (46-57%). Other misperceptions among the community such as 'TB is mainly | and 12 |
| Knowledge | caused by smoking' (86-88%), 'TB is transmitted while sharing | |
| | patients' utensils' (46%), 'TB can be prevented by quitting | |
| | smoking' (56-60%) etc. were commonly observed. | |
| | The main source of TB information of community people were | Table 13, |
| | neighbours (43-52%) and mass media (37%) followed by SSs (35- | 16,18 |
| | 42%). Nearly half of the community people (42%) did not have | |
| | adequate knowledge about TB. The probability of a maximum | |
| | knowledge score (0.77) was observed when the respondents were | |
| | aware of the TB control programme of BRAC, received information on TB from SSs, BRAC office is situated within half kilometer, | |
| ł | respondents hailed from the least poor households, and have | |
| | secondary education. However, the probability of knowledge was | |
| | only 14% when one never heard about BRAC's TB control | |
| | programme, did not receive information from SSs but received | |
| | from community people, BRAC office is situated more than half | |
| | kilometer away, and the respondents hailed from the poorest | |
| | households and had no school education. | |
| Attitudes | A majority of the respondents would counsel patients to go to the | Table 19 |
| towards TB | government hospital (52-54%), and NGO clinic (47-52%) for | |
| | availing treatment beyond asking for sputum test (29-30%) in both | |
| | Areas. Nearly half of the respondents (41-46%) in both areas were afraid | |
| | of TB, and the majority of the respondents (52-56%) reported that | |
| | community people wanted to stay away from TB patients. | |
| | Though median duration of cough of TB suspects was six weeks, | Table 20 |
| | at least one-third did not take any treatment, and two-third did not | |
| | do sputum test. Those who sought treatment, mainly received it | |
| | from informal providers such as village doctors (26-35%), drug | |
| | shop attendants (35-36%) rather than formal providers like | |
| | government hospital (21-27%), and MBBS doctors (17-20%) in | |
| | both areas. | |

Conclusion

This study showed that misperceptions regarding TB were widespread in hard-to-reach and adjacent areas among health workers and community people. Health workers were not knowledgeable enough to manage TB patients. The community was also stigmatized against TB, had poor knowledge on TB and revealed poor health-seeking behaviour. Further, there were social, economical, and geographical barriers that health workers and community people mostly confront in providing and receiving services respectively. The programme needs to address these issues to improve the TB programme in hard-to-reach areas at par with plain land.

Recommendations

- 1. The training is the primary source of TB knowledge of the SSs. Findings reveal a poor level of knowledge among them, and therefore, among the community people. Thus, the form and content of the training need a thorough overhauling in these hard-to-reach and adjacent areas. Misperceptions and stigma are widely prevalent among these communities. Sustained and culture-sensitive IEC campaigns are needed to reverse this situation. These may take the form of folk songs, popular theatre, community/courtyard meetings, etc. Cured patients/patients under treatment may be used as motivators in these various forums.
- 2. Reasons for poor motivation of the SSs need to be explored. Performance-based incentive schemes could be introduced for increasing motivation of the SSs. They may be provided with extra travel allowances since distance is a big hindrance for routine home visits in these areas.
- 3. Supportive supervision is needed to ensure early case detection and initiation of treatment. Community may also be involved in this process so as to reduce stigma and ensure early sputum examination and initiation of treatment.
- 4. Fostering collaboration between the national TB control programme and other healthcare providers, such as in the private sectors (village doctors, drug sellers) and NGOs, are also recommended so that they can refer patients to appropriate places for treatment.

Introduction

Over one-third of the global population are infected with *Mycobacterium* tuberculosis (TB) (WHO 2008), and they may turn into active TB cases at any time of their life cycle. Despite the availability of affordable and effective treatment, there were 8.8 million new cases of TB and an estimated 1.4 million deaths from TB globally (WHO 2010). This represents an intolerable burden of human sufferings and an unacceptable barrier to socioeconomic development. In fact, the increase in the incidence of TB in developing countries and its re-emergence in the developed world had led the World Health Organization (WHO) to declare TB as a 'Global emergency' in 1993. TB is a major public health problem in Bangladesh. WHO ranks Bangladesh 6th among the 22 'high TB burden' countries (WHO 2008). The overall sputum smear positive is estimated at 79.4 per 100,000 adult population in Bangladesh, and it was higher in rural areas than urban (WHO 2010). Everyday 188 people die of TB in Bangladesh (WHO 2012).

To combat the TB havocs, the government of Bangladesh (GoB), in partnership with different non-governmental organizations (NGO) including BRAC (one of the largest NGOs in the world), is implementing TB control using the Directly Observed Treatment Short-course (DOTS) strategy. The approach was intensified in 2004 with Global Fund financial support. Being in lead, BRAC alone covers 297 sub-districts (64% of the total 460) of the country. The remaining sub-districts are covered by other NGOs. BRAC's community-based DOTS model consists of female volunteers known as shasthya shebikas (SS). They work under supervision of Shasthya Kormi (paid health worker), para professionals, and physicians. BRAC assigns on average 250 neighbourhood households to each SS. As frontiers, the SSs maintain a semi-active case finding strategy, and they mobilize the community people during their routine home visits, search for TB suspects (person with prolonged cough for at least three weeks), and refer them to either BRAC union level sputum collection sub-centre or sub-district microscopy facilities, depending on the patients' convenience for sputum examination. Identified TB patients visit the SS's home daily during the initial 2-3 moths for directly observed treatment (DOT). Subsequently, patients collect medicines once a week from the SSs' homes, and the SSs ensure follow-up over the full 6-9 months course of treatment.

The National TB control programme (NTP) adopted the DOTS strategy in 1993, and expanded it progressively to the entire country by 2007. Thereafter, the case detection rates steadily increased to 72% in 2007, and treatment success has improved remarkably; the present rate is 92% 2006 which is consistent with the WHO target of over 85% (Baruaet al. 2008).

Rationale

BRAC's TB control programme includes some areas with poor communication, such as the *Char* areas (surrounded by water), hill tracts, and the coastal areas. The programme refers to these areas as 'hard-to-reach' areas. There is a paucity of information on the performance of the programme in 'these hard-to-reach areas'. So far, no independent evaluation has been conducted to explore to what extend the objectives of the programme have been achieved in terms of raising awareness about TB, and changing health-seeking behaviour of community people for appropriate and quick initiation of treatment. This is necessary because inadequate knowledge about TB and poor health-seeking behaviour may act as important barriers to service utilization and to successful control of TB. This study explored the awareness and knowledge of health workers and

community people including TB suspects regarding TB and its treatment. In addition, the study explored the health-seeking behaviour of TB suspects, and challenges for the TB programme in implementing DOTS. The findings will help further fine-tuning the programme in terms of resource allocation, programme modifications, etc., and provide a benchmark for future impact assessment.

Objectives

The study aims to investigate:

- 1. Misperceptions and knowledge of health workers and community people (suspects and non-suspects) about TB, its prevention and treatment
- 2. Health-seeking behaviour of TB suspects.
- 3. Challenges for the TB control programme in hard- to- reach areas

Methods and materials

Study areas and population

This cross-sectional survey was conducted in programme defined 'hard-to-reach' upazilas (Table 1) and upazilas adjacent to the hard-to-reach areas for comparison. The study was conducted it upazilas where BRAC's TB control programme is being implemented for many years using the SS-based infrastructure. The study included general population or non-suspect (no history of cough), TB suspects (having cough ≥3 weeks), and SS of BRAC. The non-suspects and TB suspects were aged 15 years or more.

Table 1. Distribution of hard-to-reach areas of BRAC's TB programme

| Division | District | No. of upazila/cluster | No. of <i>upazilas</i> for study |
|-------------|---|---------------------------|----------------------------------|
| Dhaka | Manikganj | 1 | 1 |
| Chittagong | Noakhali, Cox's Bazar, Bandarban, Khagrachhari, Rangmati | 16 | 8 |
| Sylhet | Sunamganj, Habiganj, Kishoreganj | 8 | 3 |
| Khulna | Bagerhat | 1 | 1 |
| Barisal | Barisal, Bhola, Patuakhali | 4 | 2 |
| Grand Total | 14 | 30 | 15 |

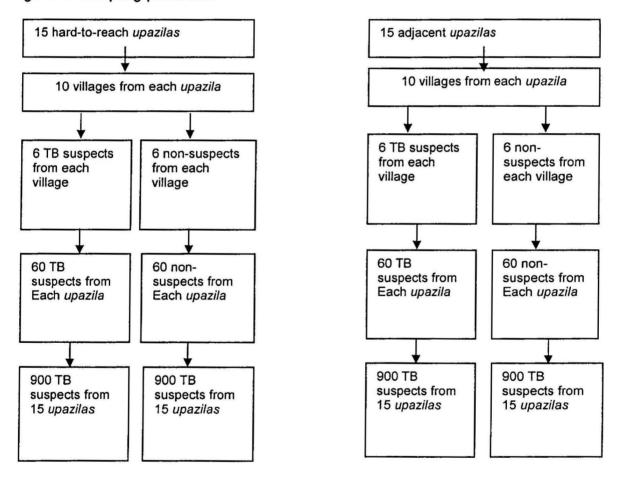

Sampling and sample size

Two stage-purposive sampling techniques were applied in the study. Initially, 15 *upazilas* from hard-to-reach areas and another 15 *upazilas* from areas adjacent to the hard-to-reach *upazilas* were selected randomly (Table 2). Secondly, 10 villages were randomly selected from each *upazila*. Three hundred villages (15x10 villages from each study area) were selected. The sample size was determined on the basis of maximum proportion (0.5) with a 5% significance level and with a 5% precision. The minimum calculated sample size for general population and TB suspects were 400 (for each group). To reduce design effects and keep provision for non-response, it was proposed to increase the sample size to 600 (400x1.5). The analysis was stratified by sex; further we added a design effect 1.5. The ultimate sample was 900 for each group. Thus, six general populations (non-TB suspects) and six TB suspects were selected from each selected village (Fig. 1 and Table 2). The SSs were selected on the basis of availability from each study village (238 SSs).

Table 2. Study upazilas

| Hard to reach UZs | Adjacent to hard-to-reach UZs |

Figure 1. Sampling procedure

Tools development

Three types of questionnaires (structured and semi-structured) were designed for collecting information from SSs, general population, and TB suspects. All the questionnaires were pre-tested in a village outside our sample for ascertaining consistency, appropriateness of languages, sequencing of questions, and to have an insight into the field operation procedure. The final questionnaire was modified and updated on the basis of field-testing. We collected information on the following variables: For SSs,

- 1) Basic profile of SSs (age, education, income, marital status, years of involvement in health services, number of patients they consult every day)
- 2) Basic knowledge on TB, causes, transmission routes, prevention, and meaning of DOTS.
- 3) knowledge retention of SSs regarding TB messages obtained from health training/refresher training, etc., (Table 3)
- 4) The lists of challenges faced by the SSs in implementing the TB control programme and the role of SSs in solving the challenges.

For general populations and suspects:

- 1) Socio-demographic profile of the respondents,
- 2) Knowledge regarding TB, diagnosis and treatment,
- 3) Knowledge about BRAC TB programme, expectation from the programme,
- 4) Attitudes towards TB, and
- 5) Health-seeking behaviour of the suspects.

Table 4 presents the TB-related information that the programme provides to the health workers in the basic training and refresher training sessions.

Table 3. Information on TB disseminated to health workers by the programme at training sessions

- 1 If anyone has cough for long time, he/she must consult doctors
- 2 Cough more than three weeks suggestive symptom of TB
- 3 TB germ is detected by sputum test
- 4 Sputum test is free of cost
- 5 Sputum test is done at government hospital/NGO clinic/medical college/chest disease hospital
- 6 TB becomes dangerous if it is not treated properly
- 7 TB medicines should be taken in front of the health workers
- 8 TB treatment is free
- 9 TB is curable when TB medicines taken regularly and treatment is completed

Data collection

Skilled interviewers were recruited and a five-day intensive training was given consisting of didactic lectures, mock interviews, role play and field practice at community level. A guideline incorporating all aspects of the study was developed for the field workers. Field trial was done in other villages outside the study areas. The training manual was developed in Bangla to guide the interviewers. The team was deployed in the study villages one day before beginning the survey for rapport building and for households listing. During this time, the villagers were informed about the purpose and activities of

the survey and their cooperation was sought. The interviewers entered the study villages and screened the households to find out the suspects (having cough more than 3 weeks) and non-suspects in one day. TB suspects were identified through house-to-house survey by asking household heads for the presence of individuals with cough for at least three weeks. Similarly, the interviewers took information about non-suspects from household heads. All the respondents were listed and required numbers of suspects (six in numbers) and non-suspects (similar numbers) were taken at random in each village.

Households were visited at three repeated intervals if the first attempt was not successful. Effective and supportive supervision was ensured on a continuous basis at all levels of the study. The investigators supervised data collection, verified the validity, accuracy, and completeness of data through spot checking and revisiting the households and individuals at random. Apart from continuous close supervision, separate groups of monitors randomly visited 10% of the households to check for accuracy and completeness of data and ensured regular feedback to the interviewers.

Ethical issue

The study was reviewed and approved by the Research and evaluation Division (RED) of BRAC. The institutional ethics committee did not have to be consulted as no invasive intervention was involved. All respondents were informed that their responses would be remained anonymous, and verbal consent was obtained.

Analysis

Data entry and cleaning was done at Dhaka head office under the supervision of the principal investigator. The data analysis was done using SPSS (version 16.0). Univariate (frequency), bi-variate (cross-tabulation) and multi-variate (logistic regression) analyses were done. The wealth quintile was measured. The wealth index developed here is similar to that used in the BDHS survey (BDHS 2007). The index is calculated using a weighted sum of household assets. We used data on household assets and characteristics of the house (source of drinking water, sanitation facilities and type of material used for flooring, roof and walls). To conclude the index we recorded these variables in a dichotomous form and used principal components analysis (PCA) (Rustein and Johnson 2004). Each variable was then assigned a weight based on its loading in the first general factor identified in PCA. The resulting score for each household was standardized with a mean of zero and standard deviation of one. The households were then ranked and assigned a score in the range of one to five; those in the first quintile assigned a score of one, those in the second quintile assigned a score of two, etc. A one score identifies the poorest households and a five score identifies the richest households. All variables are compared for the two study areas (hard-to-reach vs. not hard-to-reach). Those with a total score equal or below the median were classified as having poor knowledge while those above the median were considered to have good knowledge/awareness. All statistical significance tests were 2-sided.

Results

Sociodemographic profile of Shasthya Shebikas (SS)

The majority of SSs (57%) in the study were aged between 30 and 49 years with mean age 38 years (Table 4). One-fifth of SSs had no school education, one-third had primary, and the rest (48%) had secondary education. Half of them (53%) were involved in health services for more than six years. One-third was involved in other professions. Mean income of SSs from health services was around Tk. 666 per month. Almost all SSs (97%) of both study areas reported that they attended monthly refresher training. Seventy-five percent of SSs reported that they consulted TB suspects during the last month and 88% of them gave treatment through DOTS.

Basic knowledge of SSs regarding tuberculosis

Nearly half of the SSs (45%) reported that TB was a 'disease of male' (Table 5). The proportion was higher among illiterate SSs (49%) and who (SS) did not consult TB suspects in the last month (59%) (Annex Table 2). Only one-third of the SSs had knowledge about the germ causes TB. However, the knowledge was higher among the SSs having secondary education (40%) (Annex Table 2). They mostly reported about smoking (80%), and unhygienic environment (52%) as the main causes of TB (Table 5). Knowledge of the main transmitting route (sneezing and coughing) was comprehensive in hard-to-reach (96%) and adjacent to hard-to-reach areas (88%), (p=0.015) (Table 5). In addition, 49% reported that TB was also transmitted through the used utensils of patients. The ideas of SSs about the possible ways of prevention of TB included avoiding smoking (63%), maintaining good hygienic environment (54%), and avoiding use of patients' utensils. Only one-third (37%) had fair knowledge about BCG vaccination as preventive measure. Further, we found that one-fourth of the SSs (24%) did not know or had no correct knowledge about the meaning of DOTS in TB control (Table 5). However, knowledge about the appropriate meaning of DOTS increased with education (p=0.000) and with number of suspects they attended in the last month (p=0.016) (Annex Table 2-3).

Knowledge retention of SSs regarding nine TB-related messages

The SSs were asked to tell spontaneously what they knew about TB from basic/refresher training (Table 6). They frequently reported two messages (out of nine) such as someone should consult a doctor if one had cough for a long time (78%), and cough for more than three weeks indicates suggestive symptom of TB (88%). Knowledge retention seemed lower on diagnosis- and treatment-related messages. The same situation was observed in both the study areas. The overall knowledge retention score of SSs was estimated based on nine basic information about TB (Table 6). An adequate knowledge retention score of TB was estimated if SSs could correctly mention at least four out of nine messages. We found that 53% (55 vs 52%, >0.05, p=0.701) of SSs could remember four or more messages regarding TB (Table 6).

Table 6. Knowledge retention's ability of *Shasthya Shebika* (SS) about TB by study areas (%)

| | Hard-to- | Adjacent | All | 95% | |
|---|----------|----------|------|------------|---------|

| TB is curable if take full course of treatment | 34.9 | 30.2 | 32.5 | 26.8-38.1 | 0.411 |
| Knowledge retention score (4 & above or adequate score) | 55.0 | 52.0 | 53.0 | 49.0-58.0 | 0.473 |
| N | 132 | 136 | 268 | | |

The study also explored the association between adequate knowledge retention scores and socioeconomic variables (Table 7). The adequate knowledge retention score of TB increased with age, education level, years involved in health services, regular participation in training, and engagement in another profession, but all were not statistically significant (p>0.05).

Table 7. Sociodemographic characteristics of *Shasthya Shebika* (SS) related to an adequate knowledge retention score (%)

Adequate knowledge retention score was estimated if answered at least 4 or above (median) out of 9 (Table 6), low knowledge retention score was estimated if answered <4 out of 9 items.

Table 8 gives odds ratios of selected variables indicating probability of adequate knowledge retention score of SSs about TB. Individuals, who were older (2.12 95%CI: 1.03-4.40), had secondary school education (3.37, 95% CI: 1.34-8.49), and participated regularly in refresher training (5.14, 95% CI: 0.46-65.3) had a higher retention ability.

Table 8. Odds ratios of selected variables indicating probability of high knowledge retention score of SSs in study areas

| | High knowledge score (≥4) | | | |

Table 9 shows the probabilities about knowledge retention scores as outcomes of the effect of various combinations of factors. The knowledge was found maximum (0.81) when the SSs were older (>35 years), had minimum primary education, attended more than four TB suspects in last month, and attended refresher training regularly. The probability was the lowest (9%) when SSs had no education, attended less than four, and attended refresher training irregularly.

Table 9. Estimated probabilities of adequate knowledge of *Shasthya Shebika* (SS) regarding TB by combination of predictors

| | Combination of factors | Estimated probabilities of SS's adequate knowledge |
|----|--|--|
| 1. | Age 35+, having at least primary education, SSs attended> 4 TB suspects in last month and participating in refresher training regularly | 0.81 |
| | Age 35+, having at least primary education, burden of suspects attended ≤4 in last month and participating in refresher training regularly | 0.74 |
| 3. | Age 35+, having at least primary education, burden of suspects attended 4+ in last month and participating in refresher training regularly | 0.60 |
| 4. | Age 35+, having no institutional education, burden of suspects attended 4+ in last month and not participating in refresher training regularly | 0.45 |
| 5. | Age 35+, having no institutional education, burden of suspects attended ≤4 in last month and not participating refresher training regularly | 0.09 |

Note: Above probabilities are calculated from the estimated coefficients of Table 8 by using the following equation: $P = \exp(a + \sum b_i x_i)/[1 + \exp(a + \sum b_i x_i)]$

Activities of SSs and problems that they faced in the TB control programme

The SSs were mainly involved in referring patients to health facilities for sputum examination (46%) and ensuring DOTS during treatment (26%), rather than delivering TB messages in the community (44%) (Table 10). They also reported problems that they faced especially in hard-to-reach areas; these included difficulties in moving for TB activities (60%), and non-compliance of treatment by community patients (24%). However, poverty of SSs (28%) and lack of trust on SSs' management (20%) were noted in non-hard—to-reach areas. Lack of awareness about TB (12%), social stigma (12%), and dependency on decisions by others (12%) were cited by SSs in both areas. The SSs were asked to mention the ways to improve the TB control programme in study areas. The answers in both study areas included that the SSs of the TB control programme should be highly motivated (41%), and performance-based incentives for SSs should be provided in the TB programme (26%). However, more establishments of sputum centres (18%), more recruitment of SSs (17%), and arrangement of transport for movement (14%) were noted in hard-to-reach areas.

Table 10. Activities of *Shasthya Shebika* (SS) in TB control programme and problems faced in programme by study areas (%)

| | Hard-to- reach areas | Adjacent areas | All | P-value |
|---|----------------------------|----------------|------|---------|
| SSs delivered TB messages | 40.2 | 47.8 | 44.0 | 0.210 |

II. The community

Socioeconomic characteristics of community respondents

The majority of suspects and non-suspects in the study were aged between 30-59 years, mean 41 years (Table 11). They were predominantly Muslim (64-77%). Half of them (47-52%) could read and write letters, but the majority of them (54-59%) did not have school education. Nearly 50% of respondents were not involved in income generating activities. However, the majority of the earning people did not earn more than Tk. 5,000 per month. More than 50% of the respondents reported that their households passed deficit economy during the last year. About two-third of households had smokers. At least 10% of the households had TB patients. Two-third of the respondents had a BCG scar on the left arm. The average number of adults (>15 years) in a household was four. The main occupation of the respondents was farming (10-14%), daily labour (12-14%), and business (10-11%). The females were mostly involved in household chores or as housewives.

Knowledge of TB by general and TB suspects

The majority of the respondents (46-57%) in both the study areas reported that TB was a 'disease of male' rather than a 'disease of both sexes' (32-46%) (Table 12). Very few (8-13%) knew the germ cause of TB. However, cigarette smoking was frequently cited as main cause (86-88%). Further, in both the areas two-third of the respondents reported that TB was transmitted through sneezing and coughing. The richest knew more (74%) than the poorest (57%) (Annex Table 4). The difference was also observed by education and sex. In addition, 46% reported that TB was also transmitted through patients' utensils. Almost all the respondents had an idea about different ways of prevention of TB. Avoiding smoking (56-60%) and avoiding patients' utensils (33-36%) were cited commonly as preventive strategies. One-fourth had fair knowledge about BCG vaccination against TB (Table 12). The knowledge about BCG vaccination increased with secondary education (36%) and household assets (richest wealth quintal, 40%) (Annex Table 5). The respondents were also asked to report where TB was commonly found. Nearly half of them reported that TB was commonly found among poor people (42-49%) and in crowded areas (39-47%) (Table 12). More than 90% of respondents knew about prolonged cough as suggestive symptom of TB. On the other hand, many of them did not know other associated symptoms such as fever, weight loss, loss of appetite, weakness, and bloody sputum, etc. (Table 12).

^{*}Multiple responses

Half of them (49%) correctly knew the exact duration of cough (3 weeks) that indicates that the patients might have TB (Table 13). Young (59%), having secondary education (62%), and those living in surplus economy (63%) knew better (Annex Table 6). The poorest knowledge was observed in the poorest wealth quintile (39%). A great majority (two-third) had knowledge about government hospital and BRAC for sputum examination (Table 13). The knowledge about free sputum examination was fair (72%), however, still one-third (28%) did not know it (Table 13). The knowledge increased with education and the richest wealth quintiles (Annex Table 7). The main sources of free sputum examination were neighbours (43-52%) and mass media (38%). Only one-third received the information from SSs. More than 90% were aware of TB medicines (Table 13).

In both the areas almost 70% of the respondents had heard about BRAC's TB control programme, mainly from SSs (68-71%) (Table 14). Two-third (65%) knew about TB treatment given at community level by BRAC. Further, 75% of the respondents had knowledge about free TB treatment. Knowledge varied with education and wealth quantities (Annex Table 8). More than half of the respondents in both the areas did not know about the standard duration of TB treatment (six months).

Knowledge score

Overall knowledge was calculated based on 10 TB messages (Table 15). Knowledge score was estimated by using a median. Seven or more correct answers are defined as adequate knowledge. Around 58% of the respondents had adequate knowledge about TB. No knowledge difference was observed between the two study areas.

Table 15. Knowledge of people regarding ten TB-related messages

| Awareness of TB information | % |
|---|------|
| Awareness about both male and female get TB | 39.0 |
| Awareness about germ cause of TB | 10.2 |
| 3. Awareness about suggestive symptom (prolonged cough) of TB | 94.5 |
| Awareness about the route of transmission (sneezing and coughing) of TB | 64.4 |
| 5. Awareness about appropriate place of sputum test* | 94.5 |
| 6. Awareness about free policy of sputum test | 71.2 |
| 7. Awareness about allopathic treatment of TB | 92.6 |
| 8. about free policy of TB treatment | 74.4 |
| 9. about standard treatment lasts for six months | 47.5 |
| 10.Awareness about BRAC TB control programme | 69.4 |

Knowledge score was estimated on the basis of median. If one could answer seven or more is defined as adequate knowledge

However, the knowledge scores increased with education (p<0.0001), assets (p<0.001), awareness about BRAC's TB programme (p<0.001), exposure to doctors (p<0.001), and when BRAC TB office was situated within half kilometer of respondents' house (p<0.001) (Table 16). The study also applied logistic model to calculate odds to explore the association between knowledge scores (dependent variables), and other socio-demographic variables (independent variables) (Table 17). We found that the richest were two times more knowledgeable compared to the poorest. Controlling all the factors, we observed that the respondents were more knowledgeable when received information from SSs (Odds:3.5) compared to doctors (Odds: 2.78) and community people (Odds: 1.77).

Table 18 shows the probabilities of knowledge scores of the respondents as outcomes of the effect of various combinations of factors. The knowledge was found maximum (0.77) when the respondents were aware of TB control programme of BRAC, received information on TB from the SSs, BRAC' TB office was situated within half kilometer, respondents were richest, and at least had secondary education. However, the probability of knowledge was only 14% when one never heard about BRAC's TB control programme, had not received information from the SSs, but received information from community people, BRAC TB office was situated more than half kilometer away from the community, when respondents were the poorest and had no education.

Table 18. Estimated probabilities of adequate knowledge of the respondents regarding TB by the combination of predictors

| | Combination of factors | Estimated probabilities of respondent's adequate knowledge |
|----|---|--|
| 1. | Aware about BRAC TB programme, receive information on TB from SS, situation of BRAC TB office within half kilometer, richest and at least having secondary education | 0.77 |
| 2. | Aware about BRAC TB programme, received information from SS, situation of BRAC TB office within half kilometer, richest in wealth quintiles and having no education | 0.72 |
| 3. | Aware about BRAC TB programme, receive information on TB from SS, situation of BRAC TB office within half kilometer, poorest and at least having secondary education | 0.61 |
| 4. | Aware about BRAC TB programme, receive information on TB from SS, situation of BRAC office/SS home within half kilometer, poorest and having no education | 0.54 |
| 5. | Not aware about BRAC TB programme, not receive information on TB from SS but from community people, situation of BRAC office/SS home more than half kilometer, richest and having secondary education | 0.32 |
| 6. | Not aware about BRAC TB programme, not receive information on TB from SS but from community people, situation of BRAC office/SS home more than half kilometer, richest and no education | 0.26 |

| 8. | | 0.14 |

Note: Above probabilities are calculated from the estimated coefficients of Table 17 by using the following equation: $P = \exp(a + \sum b_i x_i)/[1 + \exp(a + \sum b_i x_i)]$

Attitudes of the respondents towards TB

In both the areas a significant proportions of the respondents (41-47%) were afraid of TB and became sad if they got TB (Table 19). Half of the respondents were not willing to talk to TB patients, and the rest would be sympathized and helpful. The majority of the respondents would tell TB suspects to go to the government hospital (52-54%), and NGO clinics (47-52%) for taking treatment. Only one-third (29-30%) in both the areas would tell the TB suspects to take sputum examination. Almost two-third of the respondents perceived that TB treatment could be taken in front of community people. The study also explored the views of community people towards TB patients. The majority reported that community people would stay away from TB patients (52-56%), or community people would want TB patient to be isolated from community people (42%).

Health-seeking behaviour of TB suspects

20). About two-third (68%) of them received treatment for cough in both the areas. The first initiation time for treatment was 10 days. The older people (>45 years) delayed in initiating treatment (Annex Table 9). Those who perceived that TB could be treated in front of people, and who did not have problem to talk to TB patients they initiated treatment for cough early (<15days) (Annex Table 9). Further, early initiation was associated with income and well off families (Annex Table 9). The respondents already received treatment for cough at least three times in both areas. Most respondents (95%) received allopathic treatment mainly from village doctors (26-35%), drug shop attendants (35-36%) rather than government hospital (21%-27%) and MBBS doctors (17-20%) in both areas. Around 5% of the respondents reported death of households' members due to prolong cough in last year. Among the TB suspects, only one-third took sputum test before interview (Table 20). Two-third of them did not have sputum test as they considered nothing serious (36-44%), lack of money (15-20%), and did not like TB medicines (12-16%). Besides the health workers (60%), the respondents were influenced mainly by neighbours (32%) and family members (27-32%) for taking sputum test. They did it mainly at BRAC (64-76%), the proportion was higher in 'not hard-toreach' areas.

Discussion

The national TB control programme in Bangladesh is performing well in recent times (NTP 2010, NTP 2011). However, BRAC, partner of NTP in community-based TB control programme through DOTS approach, is facing problems in effectively implementing the programme in hard-to-reach areas such as the fish-bow lakes, hill tracts and coastal areas. This study was conducted to investigate current status of knowledge, practice, health-seeking behaviour, etc. related to TB among the DOTS providers and the community people. Findings reveal poor state of knowledge among both the SSs and the community people. There exist substantial misperceptions among them regarding TB, and attitude of stigma against TB patients was widely prevalent. Health-seeking behaviour of patients with more than three weeks duration was poor. The geographical distance, treatment non-compliance, and lack of trust in SSs' management were identified as the major constraints in hard-to-reach areas for implementing TB programme efficiently. The implications of these for programme improvement are discussed and some relevant recommendations are made.

It is disheartening to observe that even after five years of programme implementation (under GFATM funding), various misperceptions regarding TB, its causation and prevention were widely prevalent not only among the community, but also the health workers. The most common misperception among them was that TB is 'a disease of only male' while in Afghanistan people perceived that it was a disease of female (Islam et al.

2008). Whatever the underlying reasons are, such misperception could halt the care-seeking of any person in time. Further, acquiring TB through sharing patients' used cutlery was another common misperception, as was also observed in Pakistan and Philippines (Mushtaq et al. 2010 and Navio et al. 2002). This could instigate social stigma among patients, families and communities. The TB IEC campaigns need to work more intensively to remove such misperceptions. Hence, health education might be a suitable way to fight the strong stigma attached to TB.

Again, the widely held perception in both the areas was that TB is primarily caused by smoking. Similar misperception was also reported from Ethiopia and Tanzania (Mesfin *et al.* 2005, Mangesho *et al.* 2007). They did not link TB germs to the causation of TB. The practical implication of this is that the non-smokers think themselves immune from TB and hence, would not seek appropriate care. Also, stigmatizing TB patients would have great impact on the social, psychological and mental well-being of the victim and also his/her family. This could have dire consequences in a society where informal social organizations play a pivotal role in the daily lives of individuals.

The SSs are involved in TB control activities for many years. It was surprising to find that many of them did not know the meaning of DOTS, like those in Nigeria (Dosumu 2008). This would limit SSs' ability to develop awareness among the community and motivate the suspects to seek appropriate care. Further, many of the SSs were found not to be optimally motivated to work in TB control and were not delivering TB messages in the community. In a study done in Ethiopia, the researchers found that health workers were fearful of encountering TB patients and did not want to deliver messages (Mesfin *et al.* 2005). The programme should try to find out the reasons; otherwise, it would be difficult for implementing TB control effectively by the SSs.

Even after five years of programme intervention, the knowledge of community people on TB was not of expected level. This is not surprising as knowledge is strongly rooted in tradition and culture. Similar low level of knowledge is also observed in many other TB burden countries (Sharma et al. 2007, Mangesho et al. 2007, Banerjee et al. 2000, Gelaw et al. 2001, Dong et al. 2001, Edgintonet al. 2002). The people with traditional beliefs may not visit health facilities. Even, their lack of knowledge could hamper adherence to the standard duration of treatment and could increase the multidrug resistance TB. Plausibly, their knowledge was found to increase with education, assets, awareness of BRAC TB programme, exposure to doctors, and the BRAC TB office situated within half kilometer of respondents' house. Now, the programme should focus on those who lagged behind in knowledge and awareness for rapid tangible improvements.

Further, due to low level of knowledge and awareness, stigma against TB patients was found to be quite dominant in the study communities. The main reason of social rejection is fear of transmission of the disease within the community, and TB is considered highly infectious and incurable (Islam et al. 2009). Besides, stigma appeared to be important deterrent from seeking timely care in rural Bangladesh. And its consequences are not only damaging to personal well-being of TB patients but also likely to undermine effective TB control activities. Social support can help patients overcome these barriers, with active intervention from the programme. Building local networks of cured or patients undergoing treatment to support new TB patients may be justified.

The healthcare-seeking behaviour of the study participants with more than three weeks of chronic cough was found to be poor. The majority of them did not seek help for their illness from formal place and did not do sputum test without delay as they thought that the disease was not serious. Similar thinking and inaction were also observed in Ethiopia (Yimer et al. 2009), Vietnum (Hoa et al. 2003), and China (Wang et al. 2008). Understandably, those who had school education perceived that TB treatment could be taken in front of people and could talk to TB patients face-to-face were more likely to initiate treatment early.

In conclusion, the society was constructed with widespread misperceptions regarding TB. Moreover, TB control is being implemented in hard-to-reach areas by health workers with having poor knowledge retention and with less motivated health workers. Poor health-seeking care of TB suspects goes against the programm's objectives. Further TB programme has social, economical, and geographical challenges that health workers and community people mostly confront in proving and receiving services. Programme must address all the issues immediately to sustain the current achievement of TB control programme in such areas.

Recommendations

- 1. Training is the primary source of TB knowledge of the community health workers. Findings reveal poor level of knowledge among them and the community people. Thus, the form and content of training need a thorough revision in these hard-to-reach and adjacent areas. Misperceptions and stigma are widely prevalent among these communities. Sustained and culture-sensitive IEC campaign is needed to reverse this situation. These may take the form of folk songs, popular theatre, community/courtyard meetings, etc. Cured patients or patients under treatment may be used as motivators. Reasons for poor motivation of the SSs need to be explored by the programme. Performance-based incentive schemes could be introduced for increasing motivation of the SSs. They may be provided with extra travel allowances since distance is a major hindrance for routine home visits in these areas.
- Advocacy, communication and social mobilization strategies should be tailored according to the socioeconomic characteristics of the population, with special focus on illiterate and poor for improving their knowledge and health-seeking behaviour.
- 3. Supportive supervision is needed to ensure early case detection and initiation of treatment. Community may also be involved in this process to reduce stigma and ensure early sputum test and initiate treatment.
- 4. Fostering collaboration between national TB control programme and other healthcare providers, such as in the private sectors (village doctors, drug sellers) and NGOs are also recommended so that they can refer patients to appropriate places for treatment.
- 5. A referral mechanism between the informal health providers and the public and NGO facilities should be developed and implemented.
