Abstract

This document defines a notation for specifying business process behavior based on Web Services. Web services are touted to turn the Internet into a general platform for distributed computing as required for B2B eCommerce. Web services are the glue that will link together web deployed components to form web applications. Just as there are issues with traditional component adaptation due to versioning and independent development so there are with web services. Many organizations are moving from an object-oriented paradigm for managing business processes toward a service-oriented approach; indeed, services are becoming the fundamental elements of application development. At the same time, Business Process Execution Language (BPEL) has become the standard for orchestrating these services and managing flawless execution of business process. The confluence of these trends is presenting some interesting opportunities for more flexible, cost-effective management of business processes. For our local garment sector we are developing a BPEL model so that it enhances process of the decision making of buyer.

1.0 Introduction

The goal of the Web Services effort is to achieve universal interoperability between applications by using Web standards. Web Services use a loosely coupled integration model to allow flexible integration of heterogeneous systems in a variety of domains including business-to-consumer, business-to-business and enterprise application integration. The following basic specifications originally defined the Web Services space: SOAP, Web Services Description Language (WSDL) and Universal Description, Discovery, and Integration (UDDI). SOAP defines an XML messaging protocol for basic service interoperability. WSDL introduces a common grammar for describing services. UDDI provides the infrastructure required to publish and discover services in a systematic way. Together, these specifications allow applications to find each other and interact following a loosely coupled, platform independent model.

Systems integration requires more than the ability to conduct simple interactions by using standard protocols. The full potential of Web Services as an integration platform will be achieved only when applications and business processes are able to integrate their complex interactions by using a standard process integration model. The interaction model that is directly supported by WSDL is essentially a stateless model of synchronous or uncorrelated asynchronous interactions. Models for business interactions typically assume sequences of peer-to-peer message exchanges, both synchronous and asynchronous long-running interactions involving two or more parties. To define such business interactions, a formal description of the message exchange protocols used by business processes in their interactions is needed. The definition of such *business protocols* involves precisely specifying the mutually visible message exchange behavior of each of the parties involved in the protocol, without revealing their internal implementation. There are two good reasons to separate the public aspects of business process behavior from internal or private aspects. One is that businesses obviously do not want to reveal all their internal decision making and data management to their business partners. The other is that, even where this is not the case, separating public from private process provides the freedom to change private aspects of the process implementation without affecting the public business protocol.

Business protocols must clearly be described in a platform-independent manner and must capture all behavioral aspects that have cross-enterprise business significance. Each participant can then understand and plan for conformance to the business protocol without engaging in the process of human agreement that adds so much to the difficulty of establishing cross-enterprise automated business processes today.

What are the concepts required to describe business protocols? And what is the relationship of these concepts to those required to describe executable processes? To answer these questions, consider the following:

- Business protocols invariably include data-dependent behavior. For example, a supply-chain protocol depends on data such as the number of line items in an order, the total value of an order, or a deliver-by deadline. Defining business intent in these cases requires the use of conditional and time-out constructs.
- The ability to specify exceptional conditions and their consequences, including recovery sequences, is at least as important for business protocols as the ability to define the behavior in the "all goes well" case.
- Long-running interactions include multiple, often nested units of work, each with its own data requirements. Business protocols frequently require cross-partner coordination of the outcome (success or failure) of units of work at various levels of granularity.

If we wish to provide precise predictable descriptions of service behavior for cross-enterprise business protocols, we need a rich process description notation with many features reminiscent of an executable language. The key distinction between public message exchange protocols and executable internal processes is that internal processes handle data in rich private ways that need not be described in public protocols.

In thinking about the data handling aspects of business protocols it is instructive to consider the analogy with network communication protocols. Network protocols define the shape and content of the protocol envelopes that flow on the wire, and the protocol behavior they describe is driven solely by the data in these envelopes. In other words, there is a clear physical separation between protocol-relevant data and "payload" data. The separation is far less clear cut in business protocols because the protocol-relevant data tends to be embedded in other application data.

BPEL4WS uses a notion of message properties to identify protocol-relevant data embedded in messages. Properties can be viewed as "transparent" data relevant to public aspects as opposed to the "opaque" data that internal/private functions use. Transparent data affects the public business protocol in a direct way, whereas opaque data is significant primarily to back-end systems and affects the business protocol only by creating non-determinism because the way it affects decisions is opaque. We take it as a principle that any data that is used to affect the behavior of a business protocol must be transparent and hence viewed as a property.

The implicit effect of opaque data manifests itself through non-determinism in the behavior of services involved in business protocols. Consider the example of a purchasing protocol. The seller has a service that receives a purchase order and responds with either acceptance or rejection based on a number of criteria, including availability of the goods and the credit of the buyer. Obviously, the decision processes are opaque, but the fact of the decision must be reflected as behavior alternatives in the external business protocol. In other words, the protocol requires something like a switch activity in the behavior of the seller's service but the selection of the branch taken is nondeterministic. Such non-determinism can be modeled by allowing the assignment of a nondeterministic or opaque value to a message property, typically from an enumerated set of possibilities. The property can then be used in defining conditional behavior that captures behavioral alternatives without revealing actual decision processes. BPEL4WS explicitly allows the use of non-deterministic data values to make it possible to capture the essence of public behavior while hiding private aspects.

The basic concepts of BPEL4WS can be applied in one of two ways. In *abstract process* allow specification of the public message exchange between parties only. They do not include the internal details of process flows and are not executable. It is also possible to use BPEL4WS to define an executable business process which allow you to specify the exact details of business processes.

Even where private implementation aspects use platform-dependent functionality, which is likely in many if not most realistic cases, the continuity of the basic conceptual model between abstract and executable processes in BPEL4WS makes it possible to export and import the public aspects embodied in business protocols as process or role templates while maintaining the intent and structure of the protocols. This is arguably the most attractive prospect for the use of BPEL4WS from the viewpoint of unlocking the potential of Web Services because it allows the development of tools and other technologies that greatly increase the level of automation and thereby lower the cost in establishing cross-enterprise automated business processes.

In summary, we believe that the two usage patterns of business protocol description and executable business process description require a common core of process description concepts. In this specification we clearly separate the core concepts from the extensions required specifically for the two usage patterns. The BPEL4WS specification is focused on defining the common core, and adds only the essential extensions required for each usage pattern.

BPEL4WS defines a model and a grammar for describing the behavior of a business process based on interactions between the process and its partners. The interaction with each partner occurs through Web Service interfaces, and the structure of the relationship at the interface level is encapsulated in what we call a *partner link*. The BPEL4WS process defines how multiple service interactions with these partners are coordinated to achieve a business goal, as well as the state and the logic necessary for this coordination. BPEL4WS also introduces systematic mechanisms for dealing with business exceptions and processing faults. Finally, BPEL4WS introduces a mechanism to define how individual or composite activities within a process are to be compensated in cases where exceptions occur or a partner requests reversal.

2.0 What is BPEL

Business Process Execution Language for Web Services (BPEL or BPEL4WS) is a language used for the definition and execution of business processes using Web services. BPEL enables the top-down realization of Service Oriented Architecture (SOA) through composition, orchestration, and coordination of Web services. BPEL provides a relatively easy and straightforward way to compose several Web services into new composite services called *business processes*.

3.0 Background

First, some background. BPEL builds on the foundation of XML and Web services; it uses an XML-based language that supports the Web services technology stack, including SOAP, WSDL, UDDI, WS-Reliable Messaging, WS-Addressing, WS-Coordination, and WS-Transaction.

BPEL represents a convergence of two early workflow languages; Web Services Flow Language (WSFL) and XLANG. WSFL was designed by IBM and is based on the concept of directed graphs. XLANG, a block-structured language, was designed by Microsoft. BPEL combines both approaches and provides a rich vocabulary for description of business processes.

The first version of BPEL was developed in August 2002. Since then, many major vendors have joined (including Oracle), resulting in several modifications and improvements, and the adoption of version 1.1 in March 2003. In April 2003, BPEL was submitted to the Organization for the Advancement of Structured Information Standards (OASIS) for standardization purposes, and the Web Services Business Process Execution Language Technical Committee (WSBPEL TC) was formed. This effort has led to even broader acceptance in industry.

Within the enterprise, BPEL is used to standardize enterprise application integration as well as to extend the integration to previously isolated systems. Between enterprises, BPEL enables easier and more effective integration with business partners. BPEL stimulates enterprises to further define their business processes, which in turn leads to business process optimization, reengineering, and the selection of the most appropriate processes, thus further optimizing the organization. Definitions of business processes described in BPEL do not affect existing systems, thereby stimulating upgrades. BPEL is the key technology in environments where functionalities are already or will be exposed via Web services. With increases in the use of Web services, the importance of BPEL will increase as well.

4.0 Standard Building Block of BPEL

BPEL4WS is layered on top of several XML specifications: WSDL 1.1, XML Schema 1.0, and XPath1.0. WSDL messages and XML Schema type definitions provide the data model used by BPEL4WS processes. XPath provides support for data manipulation. All external resources and partners are represented as WSDL services. BPEL4WS provides extensibility to accommodate future versions of these standards, specifically the XPath and related standards used in XML computation. [See Figure 1]

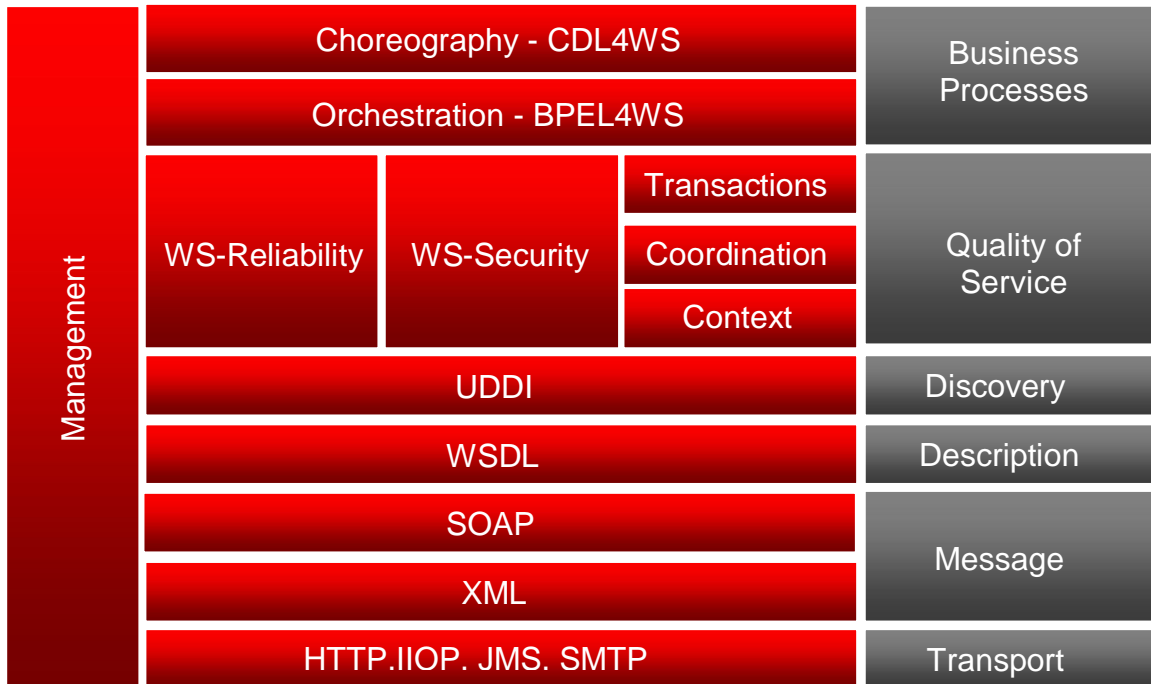

Figure – 1 [Photo courtesy – Oracle Group]

5.0 Web Service Model

Before move to Web Service Model, the term *Web services* is used very often nowadays, although not always with the same meaning. Nevertheless, the underlying concepts and technologies are to a large extent independent of how they may be interpreted. Existing definitions range from the very generic and all-inclusive to the very specific and restrictive. Often, a Web service is seen as an application accessible to other applications over the Web. This is a very open definition, under which just about anything that has a URL is a Web service. It can, for instance, include a CGI script. It can also refer to a program accessible over the Web with a stable API, published with additional descriptive information on some service directory. A more precise definition is provided by the UDDI consortium, which characterizes Web services as “*self-contained, modular business applications that have open, Internet-oriented, standards-based interfaces*”. This definition is more detailed, placing the emphasis on the need for being compliant with Internet standards. In addition, it requires the service to be open, which essentially means that it has a published interface that can be invoked across the Internet. In spite of this clarification, the definition is still not precise enough. For instance, it is not clear what it is meant by a modular, self-contained business application. A step further in refining the definition of Web services is the one provided by the World Wide Web consortium (W3C), and specifically the group involved in the Web Service Activity: “*a software application identified by a URI, whose interfaces and bindings are capable of being defined, described and discovered as XML artifacts. A Web service supports direct interactions with other software agents using XML-based messages exchanged via Internet-based protocols*”. The W3C definition is quite accurate and also hints at how Web services should work. The definition stresses that Web services should be capable of

being “defined, described, and discovered,” thereby clarifying the meaning of “accessible” and making more concrete the notion of “Internet-oriented, standards-based interfaces.” It also states that Web services should be “services” similar to those in conventional middleware. Not only they should be “up and running,” but they should be described and advertised so that it is possible to write clients that bind and interact with them. In other words, Web services are components that can be integrated into more complex distributed applications. This interpretation is very much in line with the perspective we take in this book, and explains why we place so much emphasis on the need to understand middleware as the first step toward understanding Web services.

The W3C also states that XML is part of the solution. Indeed, XML is so popular and widely used today that, just like HTTP and Web servers, it can be considered as being part of Web technology. There is little doubt that XML will be the data format used for many Web-based interactions. Note that even more specific definitions exist. For example, in the online technical dictionary *Webopedia*, a Web service is defined as “*a standardized way of integrating Web-based applications using the XML, SOAP, WSDL, and UDDI open standards over an Internet protocol backbone. XML is used to tag the data, SOAP is used to transfer the data, WSDL is used for describing the services available, and UDDI is used for listing what services are available*”. Specific standards that could be used for performing binding and for interacting with a Web service are mentioned here. These are the leading standards today in Web services. As a matter of fact, many applications that are “made accessible to other applications” do so through SOAP, WSDL, UDDI, and other Web standards. However, these standards do not constitute the essence of Web services technology: the problems underlying Web services are the same regardless of the standards used. This is why, keeping the above observations in mind, we can adopt the W3C definition and proceed toward detailing what Web services really are and what they imply.

Web services usually expose operations of certain applications or information systems. Consequently, combining several Web services actually involves the integration of the underlying applications and their functionalities. Web services can be combined in two ways:

- Orchestration
- Choreography

5.1.1 Orchestration

In orchestration, which is usually used in private business processes, a central process (which can be another Web service) takes control of the involved Web services and coordinates the execution of different operations on the Web services involved in the operation. The involved Web services do not “know” (and do not need to know) that they are involved in a composition process and that they are taking part in a higher-level business process. Only the central coordinator of the orchestration is aware of this goal, so the orchestration is centralized with explicit definitions of operations and the order of invocation of Web services. [See Figure 2 in next page]

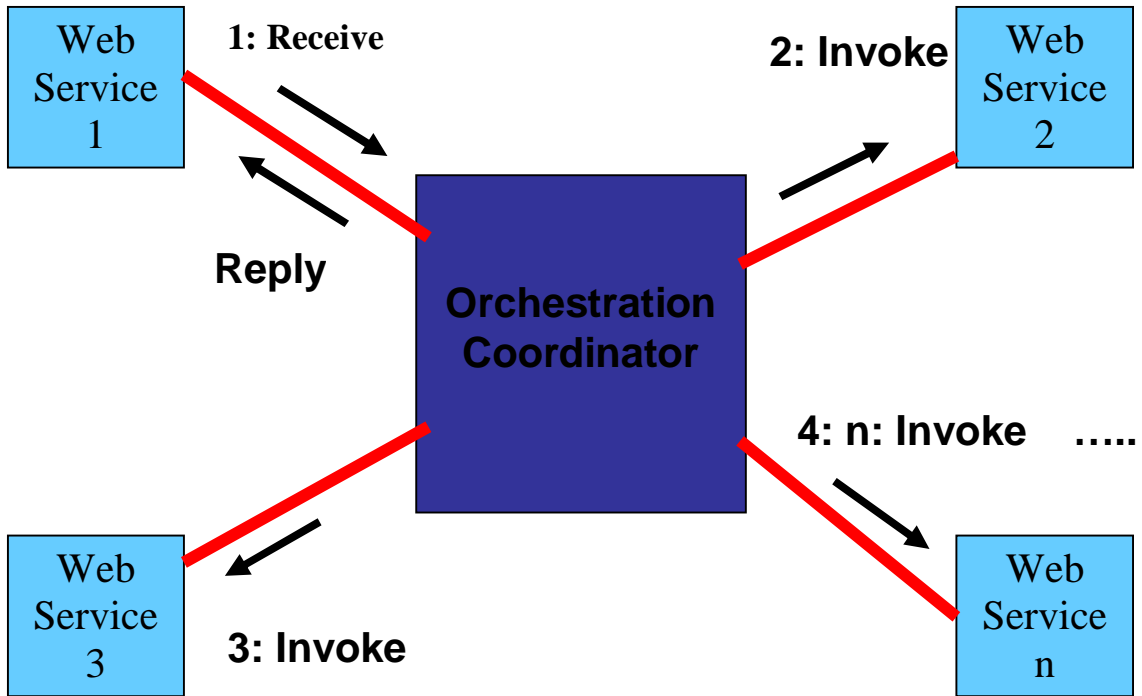

Figure 2

5.1.2 Choreography

Choreography, in contrast, does not rely on a central coordinator. Rather, each Web service involved in the choreography knows exactly when to execute its operations and with whom to interact. Choreography is a collaborative effort focusing on the exchange of messages in public business processes. All participants in the choreography need to be aware of the business process, operations to execute, messages to exchange, and the timing of message exchanges. [See Figure 3 in next page]

Figure 3

From the perspective of composing Web services to execute business processes, orchestration is a more flexible paradigm and has the following advantages over choreography:

- ▶ The coordination of component processes is centrally managed by a known coordinator.
- ▶ Web services can be incorporated without their being aware that they are taking part in a larger business process.
- ▶ Alternative scenarios can be put in place in case faults occur.

5.2 Orchestration or Choreography

BPEL supports two different ways of describing business processes that support orchestration and choreography:

- **Executable Processes:** The logic and state of the process determine the nature and sequence of the Web Service interactions conducted at each business partner, and thus the interaction protocols. While a BPEL4WS process definition is not required to be complete from a private implementation point of view, the language effectively defines a portable execution format for business processes that rely exclusively on Web Service resources and XML data. Moreover, such processes execute and interact with their partners in a consistent way regardless of the supporting platform or programming model

used by the implementation of the hosting environment. They follow the orchestration paradigm and can be executed by an orchestration engine.

- **Abstract Business Protocols:** A BPEL4WS process can define a business protocol role, using the notion of *abstract process*. For example, in a supply-chain protocol, the buyer and the seller are two distinct roles, each with its own abstract process. Their relationship is typically modeled as a partner link. Abstract processes use all the concepts of BPEL4WS but approach data handling in a way that reflects the level of abstraction required to describe public aspects of the business protocol. Specifically, abstract processes handle only protocol-relevant data. BPEL4WS provides a way to identify protocol-relevant data as *message properties*. In addition, abstract processes use non-deterministic data values to hide private aspects of behavior. They follow the choreography paradigm.

6.0 Business Process

Figure 4

Above picture [Figure 4] is a typical business process. We can call it a segment or portion of a business chain. In a business chain, more than one manufacturer may be involved. In many cases buyer becomes a supplier and this way going until it reaches to the ultimate customer. As this figure is related to our thesis paper so it's really necessary to understand how a buyer becomes a supplier. Suppose AA gives an order to BB and only BB can give what AA wants. At this point AA is buyer and BB is supplier. But to make shape what AA wants BB needs to depend on CC. Now BB becomes buyer and CC becomes supplier. This process will be going on until the product is finished and ready for consumer.

7.0 Design

Let's talk about the scenario. In Bangladesh there are more than six thousand and five hundred garments. Let say, a buyer wants to place an order to the local garment manufacturer → that put 'X' brand button on 1000 pieces of shirt.

7.1.1 Old System

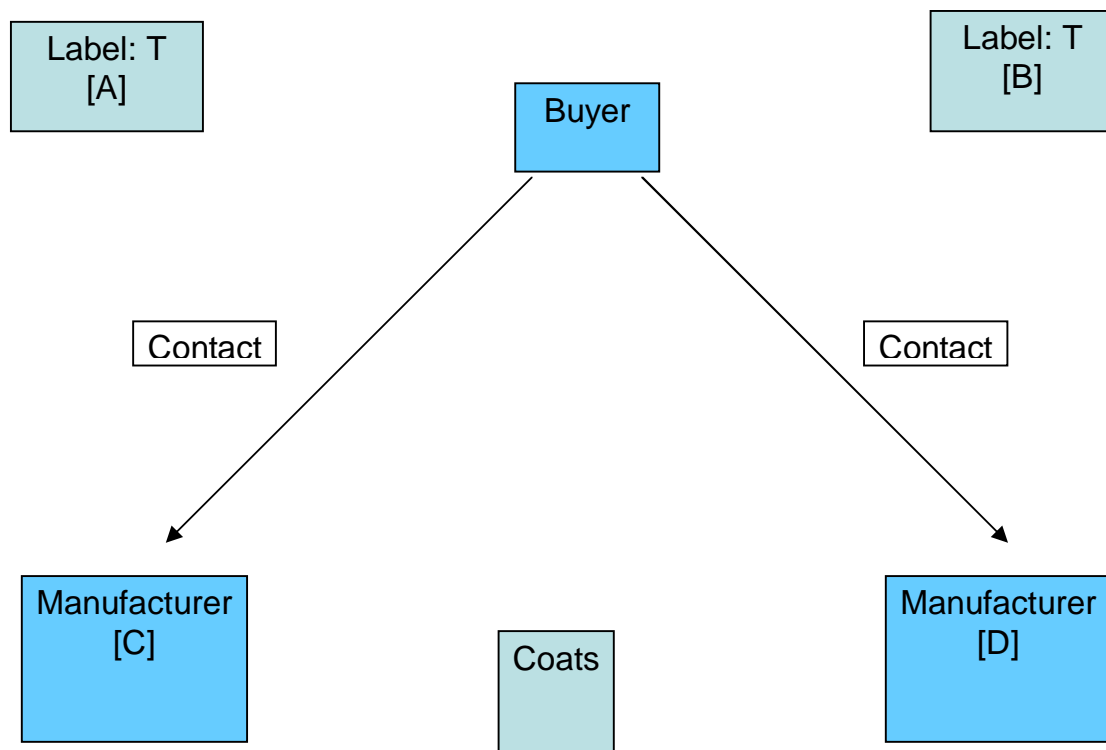

Figure 5

According to old system buyer [let say, XYZ Company] first needs to find out which companies add [put] button on the shirts. Then it needs to find out whether they are capable of taking this order. Because there are many companies who don't have the capacity to put buttons on 1000 pieces of shirt within 10 days. After finding out who are capable it needs to make an agreement with that company about price, delivery date etc.

This is really a difficult task if we have 100 choices in front of us and we have to go through 100 records to find-out optimal or best one.

7.1.2 New System

Basically BPEL may apply to various type of business sector for making their web service system efficient and a smart one. In our project for implementation we took the garments sector where the BPEL can be implemented in a large scale. Now let's take a look to our design for garments sector. To make it more clear we have divided the total process in some steps. In the scenario we have made field for Buyer, Manufacturer and Brand Button X maker [we use in picture Label]. Here manufacturer and label has multiple blocks just because we are making the system when there are more than one party involved. Again if we can show it for two companies than it will be applicable in n number of companies.

1st Step:

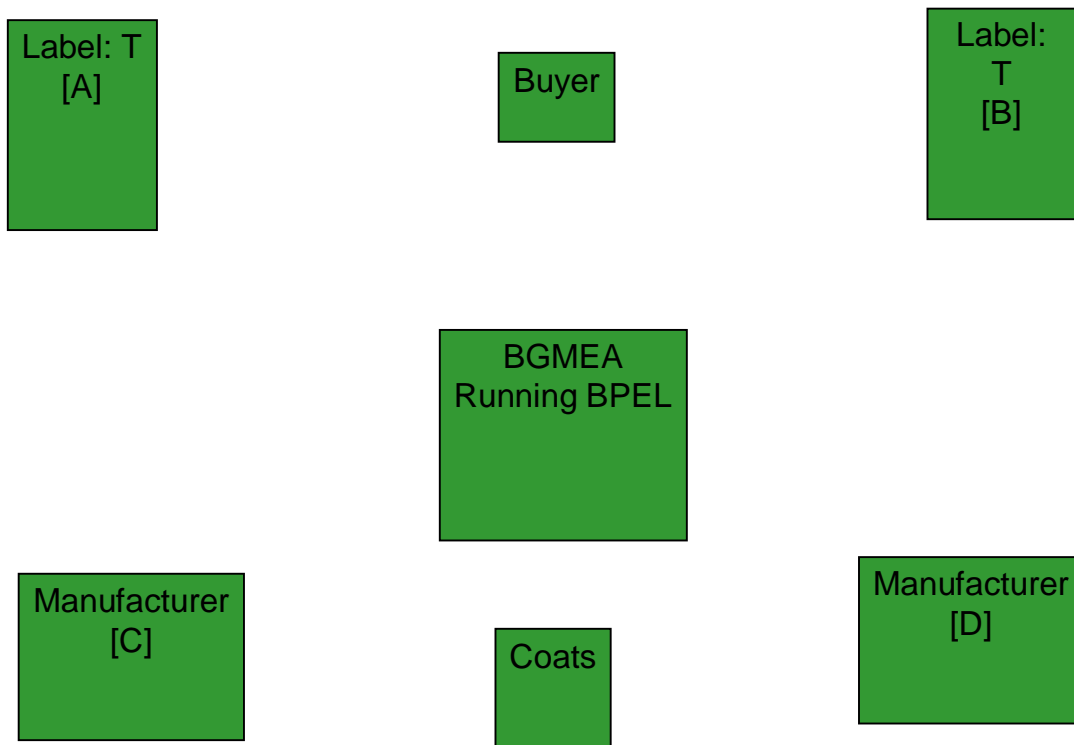

Figure T

This is basically the initial step. Here we have just put the variables who are directly involved in our design. The software we are designing that will run on BGMEA local server. From there every buyer will access it to find out which one is optimal in case of making a business contract. Now we have put a variable called 'Coat' in our environment. This is because actually a company except like coat make contract with other company when they have an order. But coat or something like this company make a long-term contract with a supplier i.e. five years or more. This type of companies will also be benefited from our system. Here we can see a normal and very simple environment for the garments sector. Here we took only the Buyer segment, Manufacturer segment, Sub manufacturer segment (Label maker or may be Button maker) and off course where the BPEL system will run. To make this design phase, at first we face the problem that where the BPEL system will be integrated? In our focus at the most efficient way to make the BPEL system very useful to all the segments or sub sector of garments manufacturer is to integrate the system to the BGMEA. That means the BPEL system will work centrally which will give the opportunities to all the sectors to take the support of BPEL system. Now what we have done in our project is: There are buyers who give the orders for the different categories of garments product. Now the problem is the foreign buyers have to determine that which manufacturer can give him the best for his or her order. Here BPEL system will take care of it. In BPEL system, there have the entry of different manufacturer and their data, which will accumulate their current position of working. Now when a buyer want to find out a manufacturer he or she has to give his requirements through the BGMEA and BGMEA will make the decision with the help of BPEL system and give the result which is the best for his or her order. In the same way the manufacturer will find out the sub manufacturer which will provide the materials like: Buttons, Label, Knitting, Wash, and Packaging etc.

2nd Step:

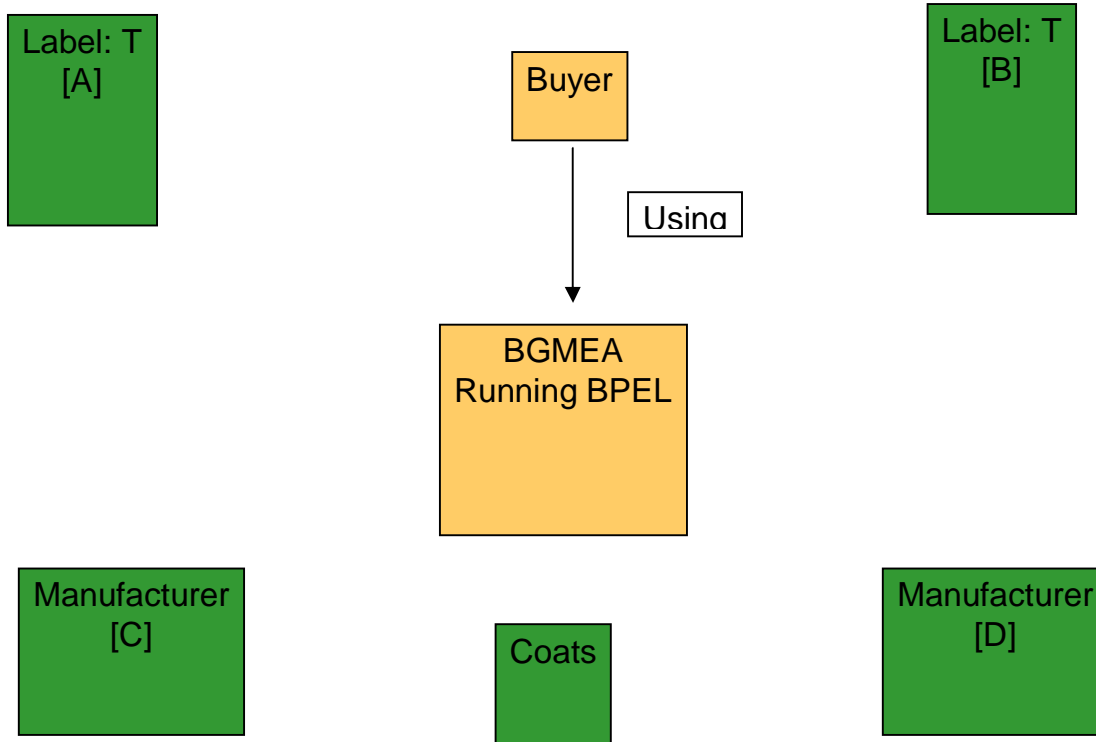

Figure 6

Here the buyers want to contact with the manufacturer of Bangladesh and which are registered with the BGMEA. Here the manufacturer's evaluation or their current working situation is stored to make the contact or business with the buyers. In this model a buyer wants to order some garments products. At first the buyer has to find out the suitable manufacturer to make the business. To find out buyers best manufacturer, at first the buyer has to log on to the BGMEA site where the BPEL system is integrated. In this BPEL system, which we can see as a web service, that has to be very helpful, or we can say very handy for the buyers to place his or her requirements. Here the buyer will places its requirements like: Category of products, Unit cost of the products, dead line to delivery of the order etc.

3rd Step:

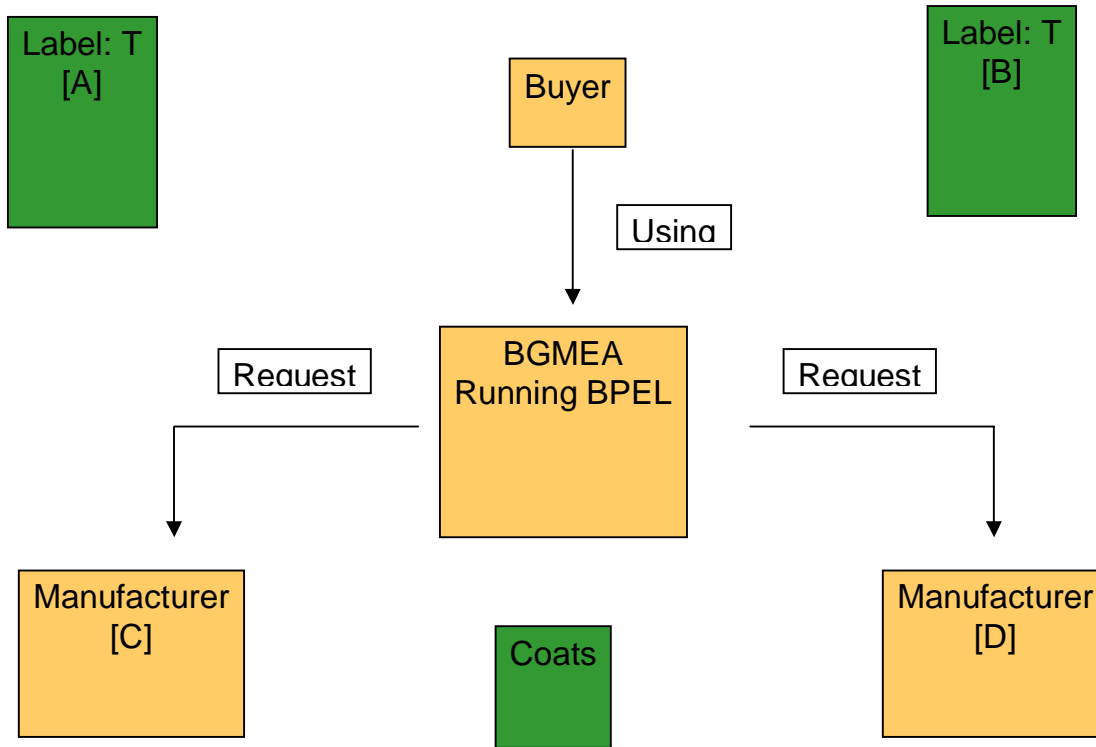

Figure 7

Here after getting the knock of a buyer the BGMEA, which is actually working with the BPEL system going to the next step. After getting the requirements of the buyer the BPEL now will request to the entire manufacturers that are under the BGMEA to accept the new order. Actually this is notified for the manufacturer that there is a new buyer in the market. We can say it is the invitations for the entire manufacturer to get the order. Now as it is a web service system and the BPEL system will take care about the result that who is going to take the order the manufacturer has to provide their situation to the BGMEA that the BPEL system can evaluate among the manufacturer.

4th Step:

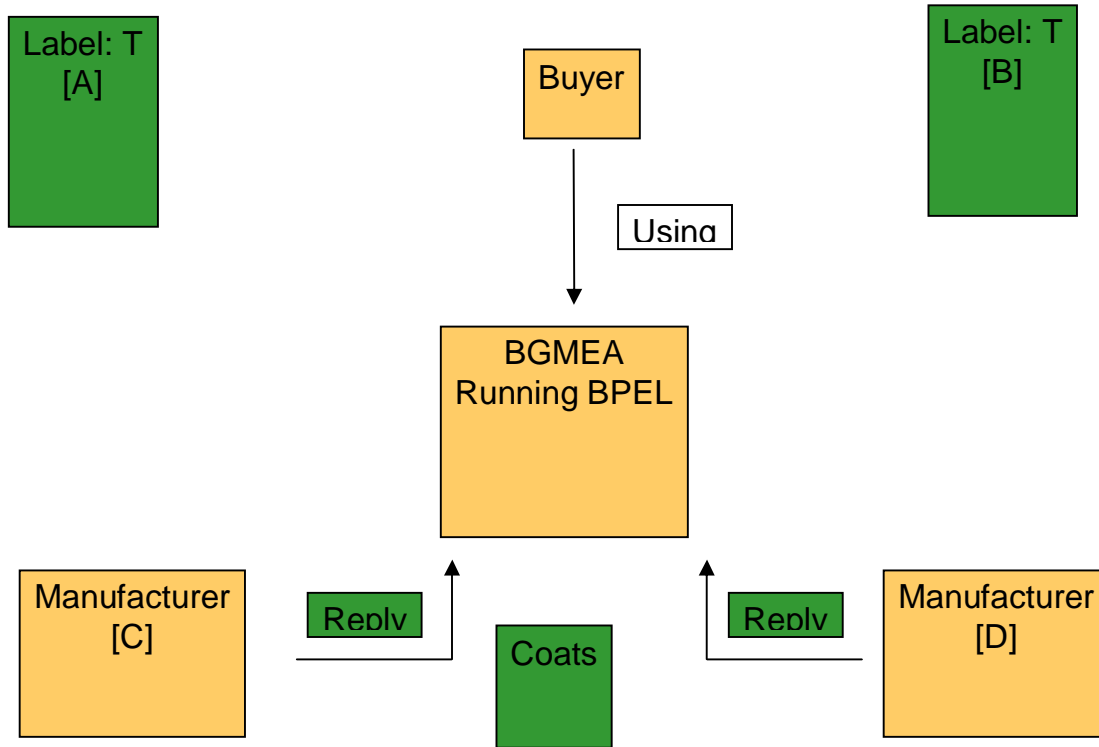

Figure 8

Here after getting the invitation to get the order the manufacturer has to react. As it is automated web service system and the BGMEA has the requirements of the buyer and through the BPEL system the BGMEA has to make a decision or show a path to the buyer to proceed to the order; the BPEL system now need to know the current workflow of the manufacturer and their capabilities of making products and of course their required price for each unit. Because with these information's the BPEL system will find out which manufacturers can take the order or which manufacturer can fulfill the order according to the buyer's requirements and deliver the products.

5th Step:

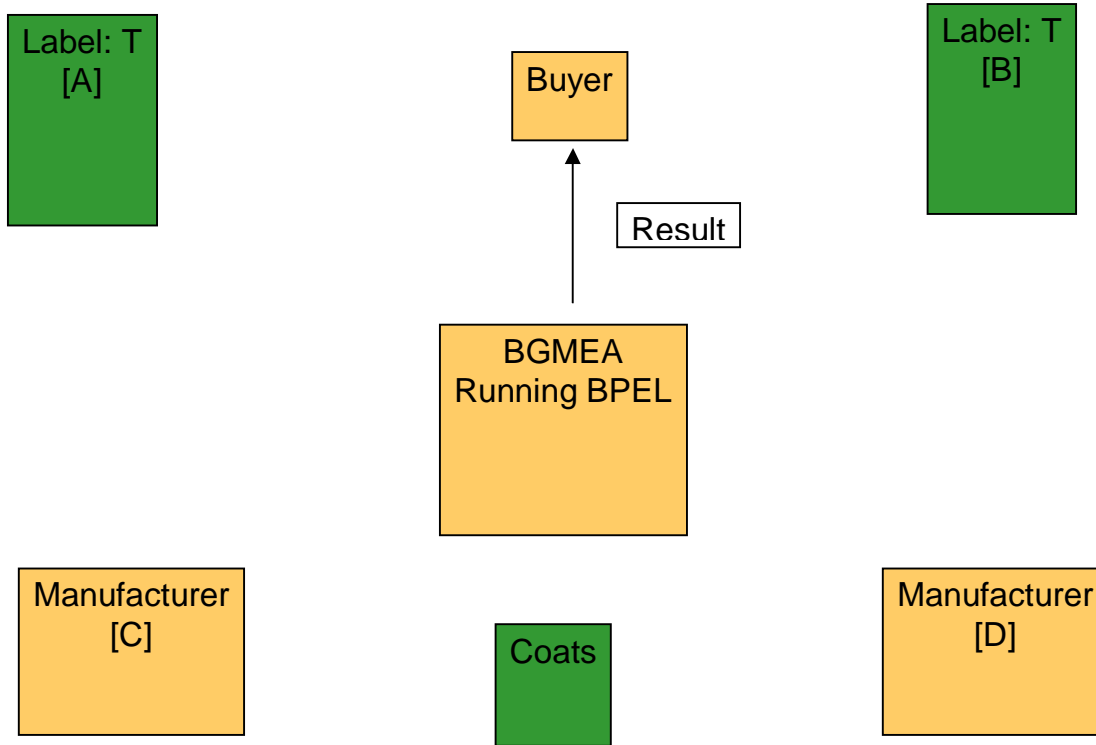

Figure 9

As the manufacturer give the reply and their current working status and their current capabilities. Now the BPEL system find out the manufacturer that can take the order of that buyer and that also the best for the buyer who can supply the goods with in the dead line and with the optimal unit cost too. Now the BPEL system will show the list of that manufacturer to the buyer with the contact address and other stuffs. This main task of the BPEL for the buyer. And now the buyer has to make the contact with that manufacturer and that connection is established through the B-to-B communication system that is shown in the next diagram:

6th Step:

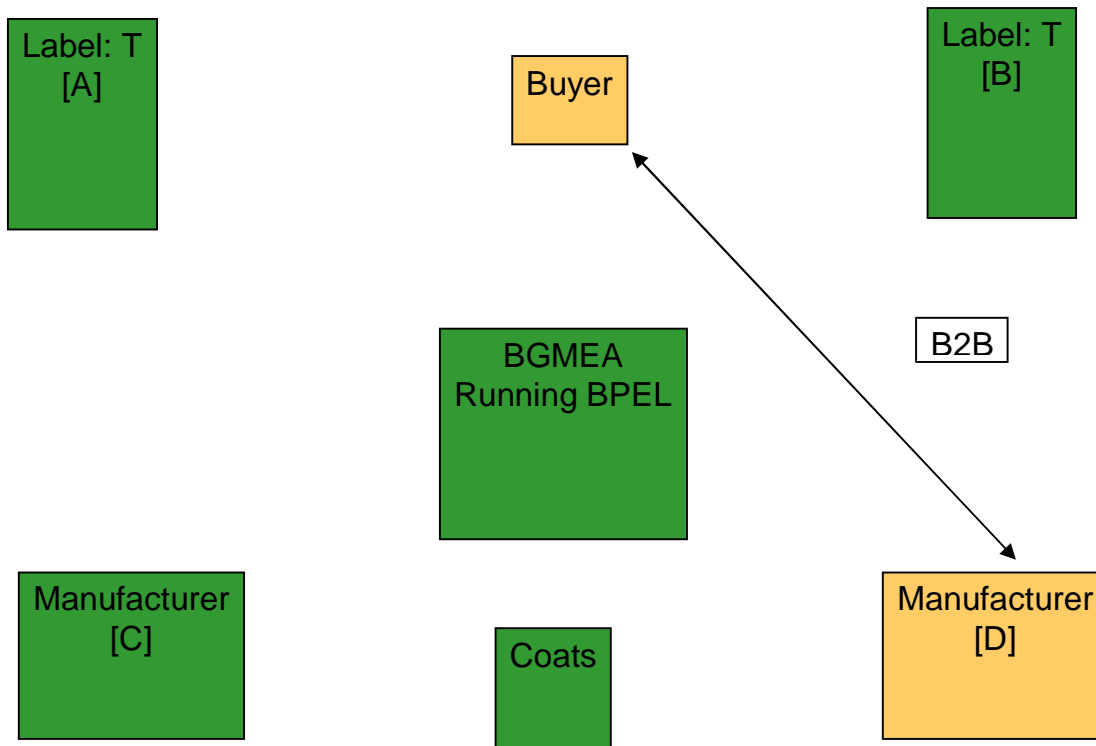

Figure 10

As the system has replied that Company D is optimal for that buyer in terms of price and supply deadline it will implement a B2B with that company. One think make sure that it up to the company whether it will implement B2B with the resulted company. Up to this XYZ Company has found out with which it will make contract.

Now as we know and I described earlier that the manufacturer not do the entire components by it self. The different producers make different portion of the garment products. Here we call these producers as the sub manufacturer. Hare the manufacturer also have to find out these sub manufacturers that can make the buttons or labels or packaging etc. For finding this sub manufacturer we also use the BPEL system. Here the manufacturer act as a buyer and sub manufacturer acts as a manufacturer. The manufacturer has to mace the order and the sub manufacturer has to supply for the manufacturer. Here the tasks are done same as we do for the buyer and manufacturer.

To see this process in our design we keep the whole process as same as earlier we did for buyers and manufacturer. Here the manufacturer work as buyer done before and sub manufacturer used for manufacturer.

7th Step:

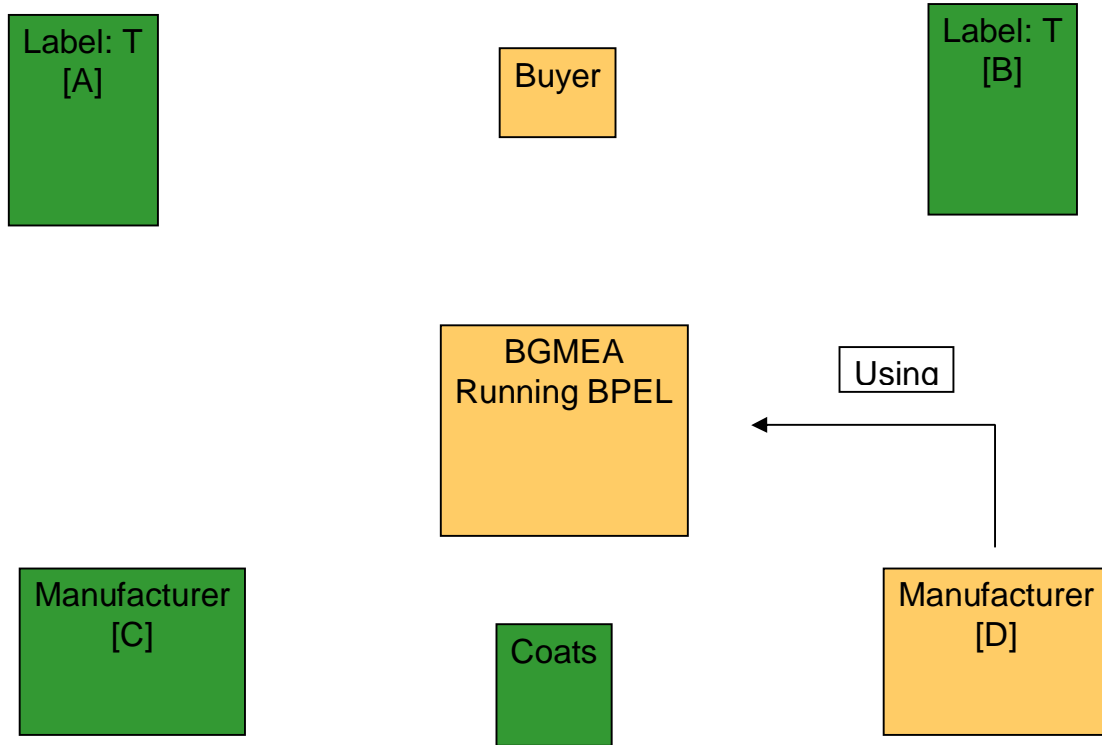

Figure 11

As we can see in this diagram that here the manufacturer is connect with the BGMEA where the BPEL system is integrated. Here the BGMEA store the information of the sub manufacturer who makes different parts of the garment product and those are stored in categorized way. While the manufacturer log on to the BGMEA web services, the manufacturer has to select the category of the type of product. According to select the category of the product the manufacturer will be shown a list of manufacturer of that product with the capacity of that sub manufacturer. On that list the manufacturer can select one or more or all the sub manufacturer to make know that who can get the order. For our design let's take the label makers as our demo category.

8th Step:

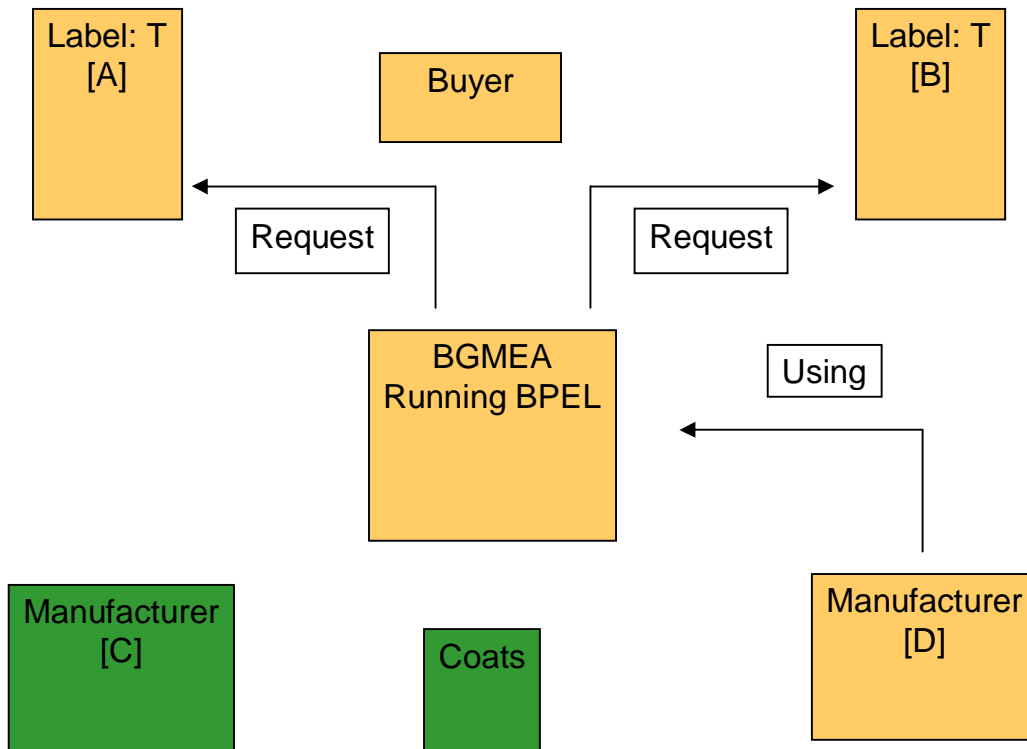

Figure 12

Here we can see the BGMEA make a request to the selected label makers. The manufacturer selects these label makers. Here the manufacturer gives the quantity and also the dead line for the product supply. This information are needed to find out the possibilities to get the order for the sub manufacturer. This price and the dead line is the delivered by the manufacturer and that according to the price and the dead line of the buyer gave to him. Now the evaluation will be happen with in these sub manufacturers.

9th Step:

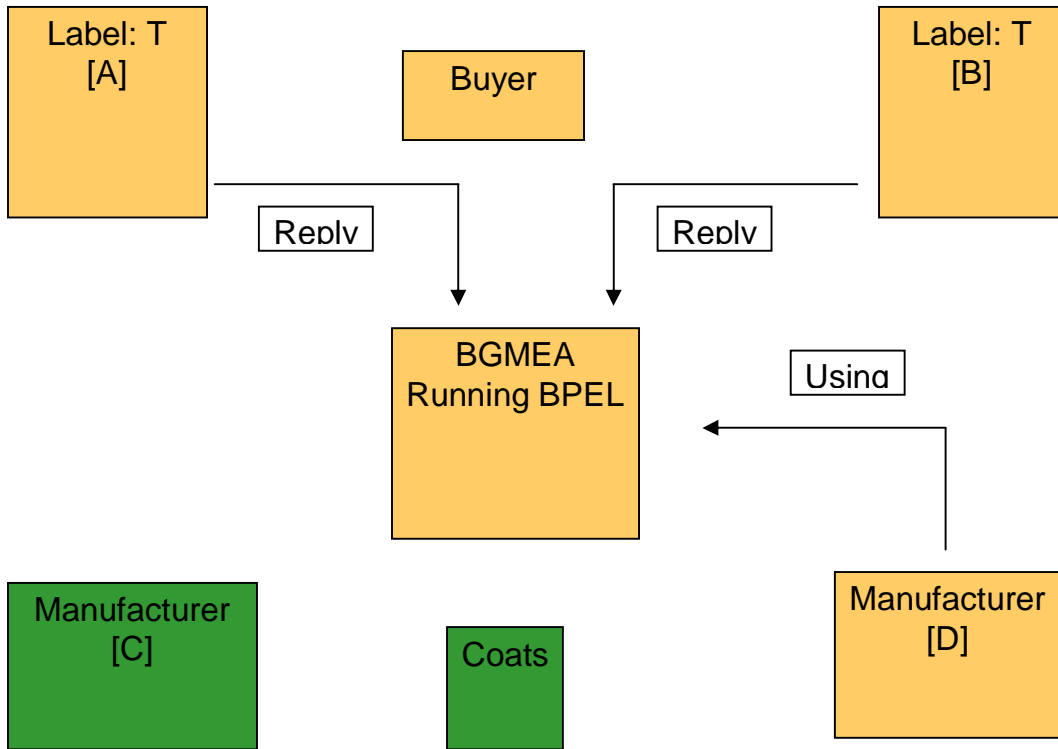

Figure 13

Here the reply from the label maker. The label maker gives the information of their company id, per day capacity, current working status etc. The BGMEA will manipulate this information by checking out with the requirements of the manufacturer. Here in BGMEA the BPEL need to know their current work flow to make decision that whether they can make the order with in the dead line of the order and also to find out the company is free to do the work for the manufacturer.

10th Step:

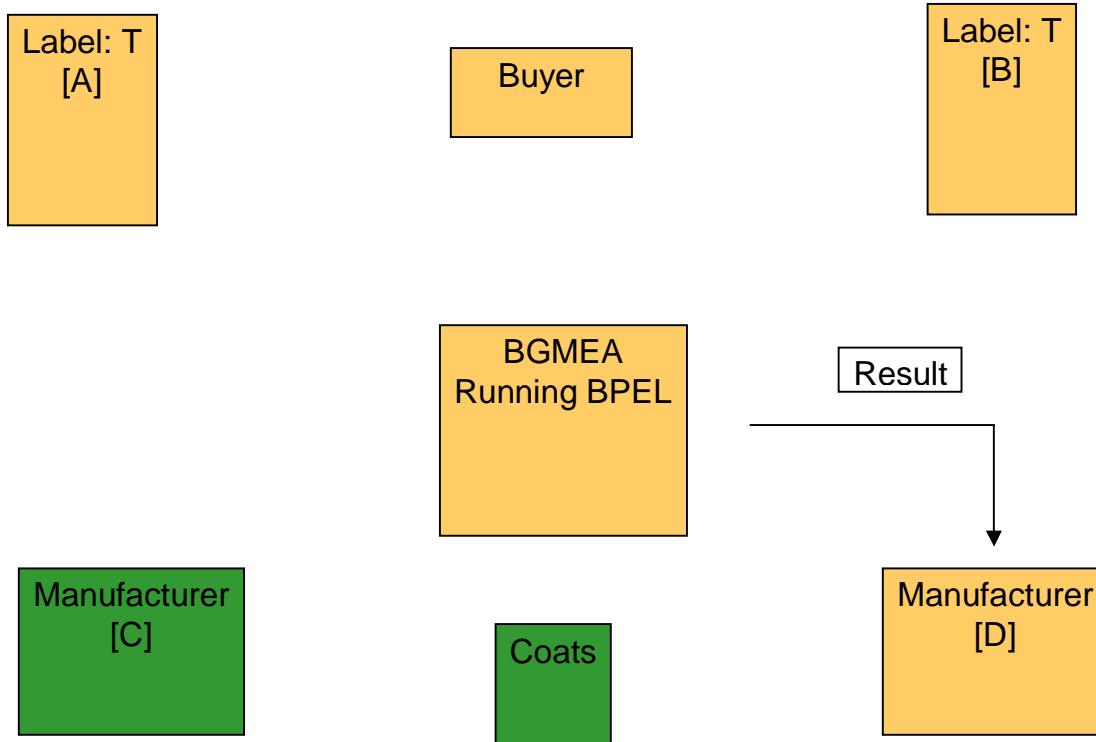

Figure 14

Now the BPEL system has the reply from the respected sub manufacturer. With the reply the BPEL system also get the current data of that selected sub manufacturer. BPEL system now checks the requirements with the selected sub manufacturer data. Here it checks about the quantity with the sub manufacturer's ability to make products and it also checks the unit price that the sub manufacturer provides. Then it selects the optimal one. This result now will show to the manufacturer. Here the manufacturer also gets the contact address of that sub manufacturer. That means the less price offered by the sub manufacturers. Actually this is the major interest for the BPEL system o make the optimal solution for the order maker. It will help him to choose his sub manufacturer. This will be the best for him.

11th Step:

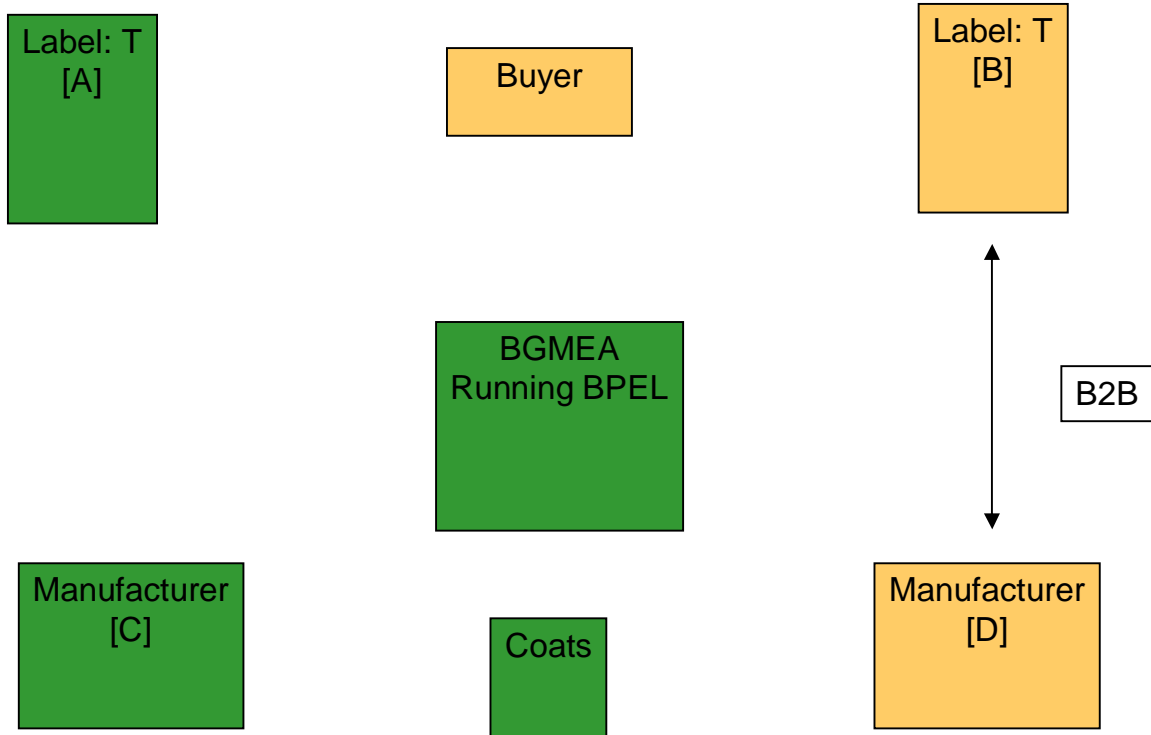

Figure 15

Let assume that the manufacturer is satisfied with the result. That means the manufacturer wants to place his or her order to that sub manufacturer. Then it will make contact with that company and the rest of the procedure will be continued in the normal Business to Business (B2B) process.

12th Step:

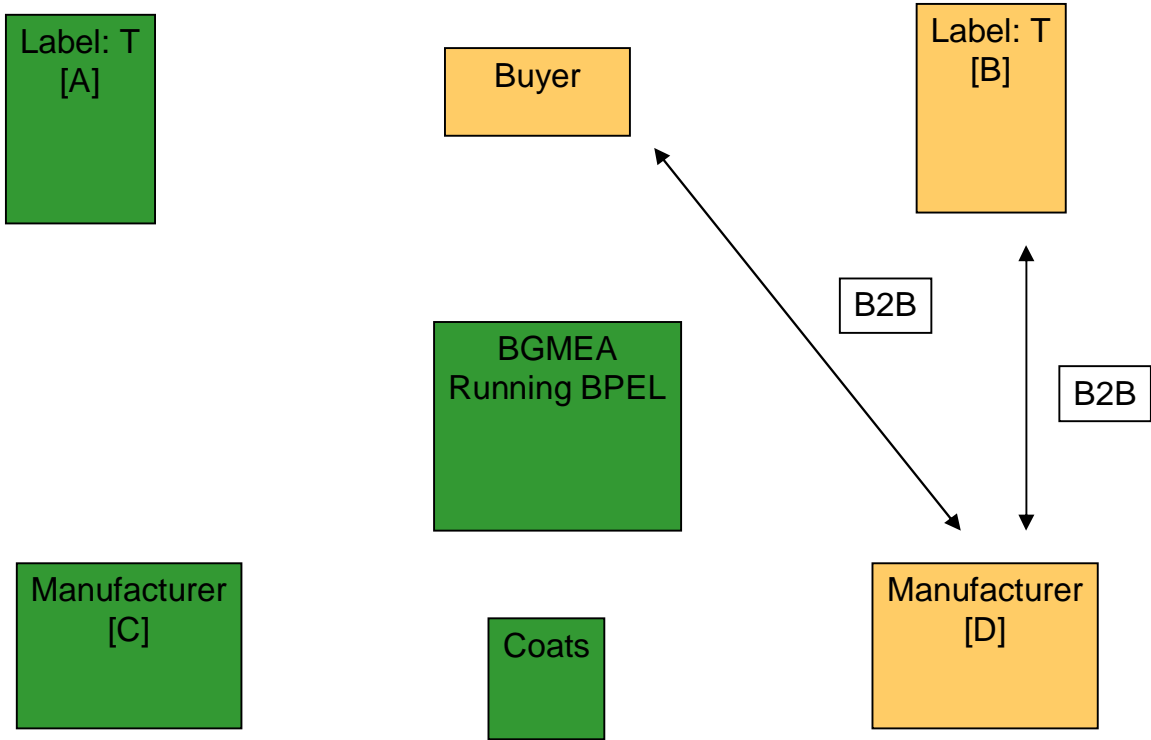

Figure 16

This picture is the ultimate business process between parties. With a little bit of information, provided by the buyer, the system doing job which reduce the pressure from each of the company when it is in buyer position and it needs a suitable supplier. This the simple B2B process between the buyer and also the sub manufacturer. Hare may have more connection of B2B with different sub manufacturer like: Button maker, Washing, Packaging etc.

7.1.3 Typical Database

Reg_Num	Name	Type	Link	Per_Cap	Database

Figure 17

For our thesis, as the scenario demands we have made a simple database design. This database will run under BGMEA. In the database design, we put the Registration Number [in short Reg_Num] as a primary key. Because two companies don't have the same registration number. Name field is for keeping the name of the company. Type field, to identify what type of company it is – is it button or knitting. Link is for accessing the company website. Per_Cap [fully, Per day Capacity] is for keeping track which company produces how much in a day. There is one reason for keeping this information in

BGMEA server rather than keeping it to all companies local server. Local company may manipulate the information to attract buyer i.e. they show a wrong per day capacity and a buyer found oh! X produces 200 units a day where as Y produces 100 units. But the real fact is Y gives the right information where as X gives a wrong one to attract buyer, actually X produces 90 units per day. This will cause a serious loss for a buyer again the new system will generate a wrong result. So from our point of view we think this will be in BGMEA server and if any company thinks that they have changed their per day capacity to a new one they will make a request to BGMEA to upload their new per day capacity and BGMEA will do that after making necessary test/query to that company. The field, Database is for the location of each company's local database, from where our new system will read/retrieve information.

7.2 Old System vs New System

In case of old system, it is totally,

- Time consuming: Need to spend more time finding out optimal one.
- Costly: Need to contact with the companies.

In case of new system, it is totally,

- Time saving: Only the time needed by the system to process the information.
- Cost effective: Require some mouse clicks and keyboard input.

8.0 The Way Software Works

8.1.1 User-end

This is the portion where user I mean buyer will be involved.

8.1.1.1 First Phase

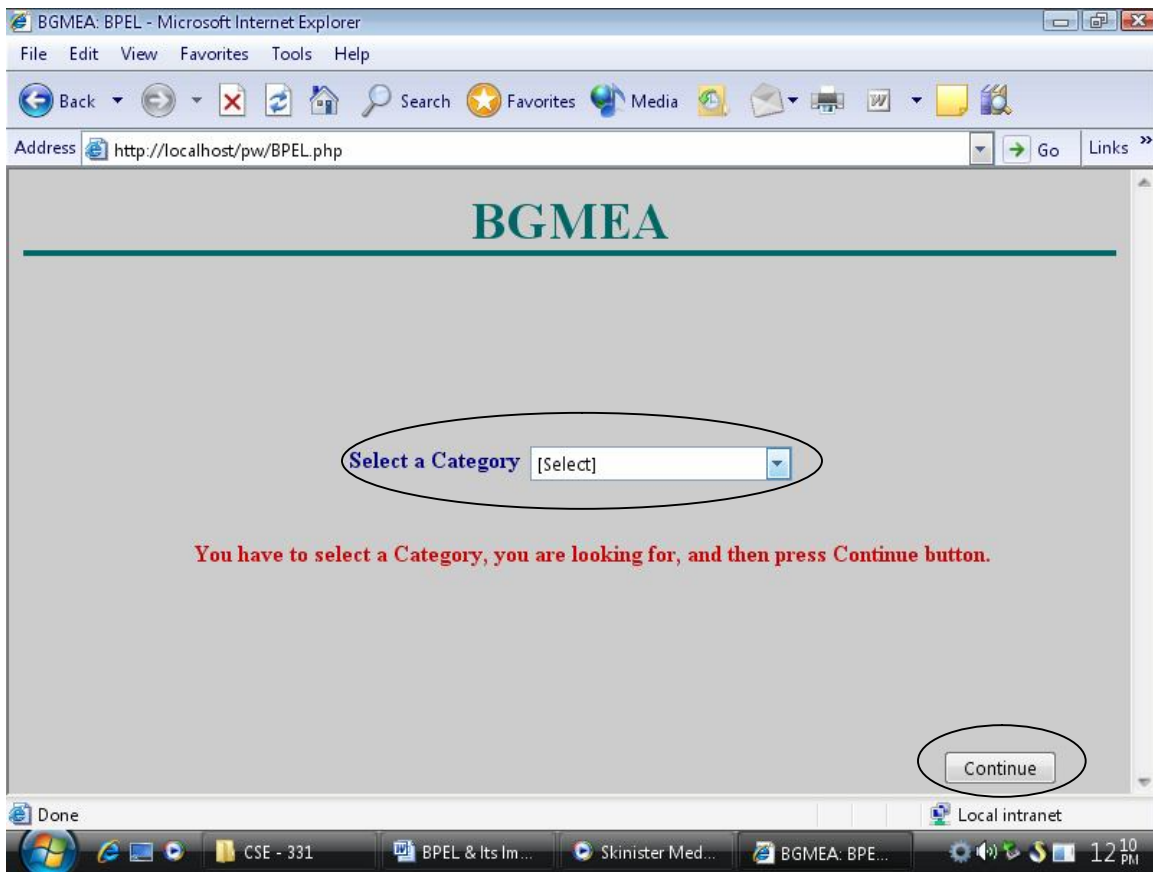

Figure 18

When the software will run at BGMEA’s own server, at the beginning user will find the above page. User needs to select a category and then needs to click on “Continue” button. User will move to new page.

8.1.1.2 Second Phase

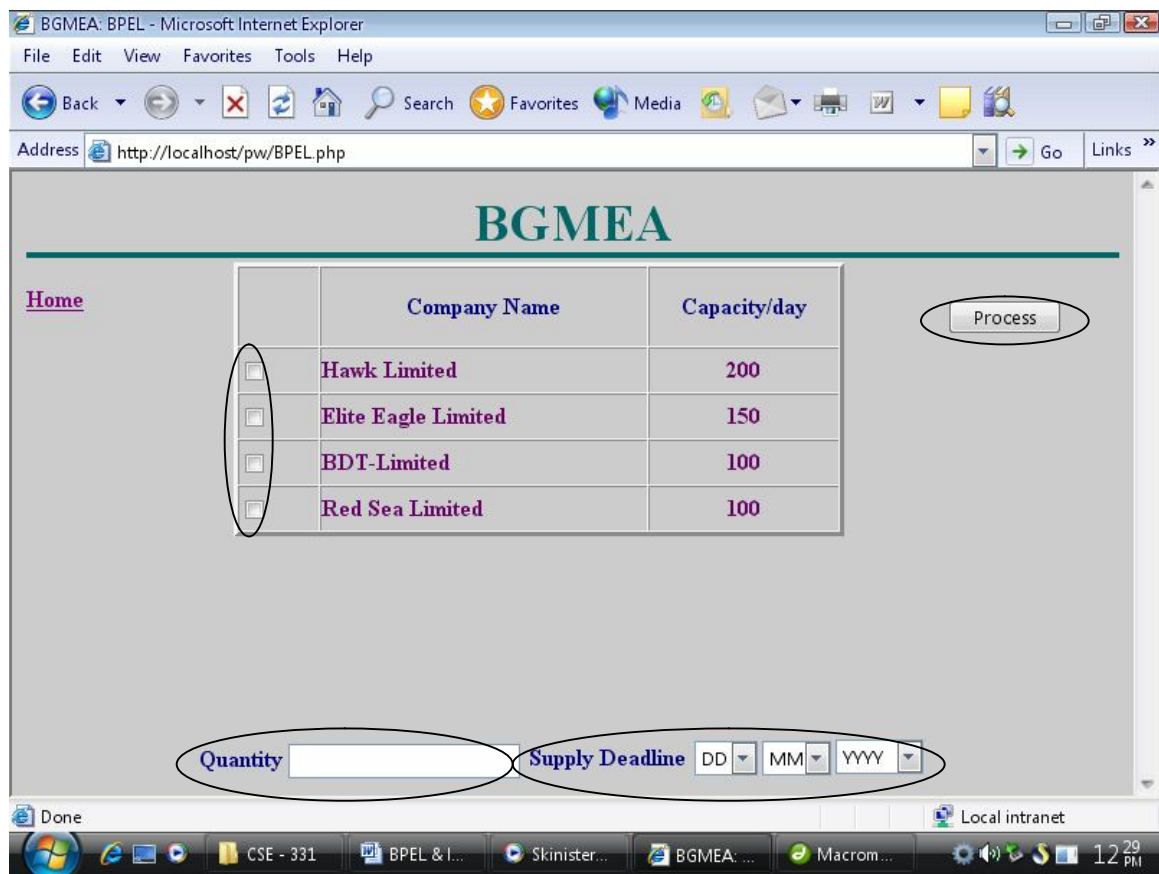

Figure 19

From the last page, if user selects “Button” [in the category field] and click on “Continue” then the above page will be shown. Here, we see company name with its per day capacity. There is a checkbox on the left side of each company name. User needs to select as many as s/he wants to select. Then s/he has to provide “Quantity”, his or her company is going to order. Then need to choose a deadline and then click on “Process” button. User will move to next page.

8.1.1.3 Third Phase

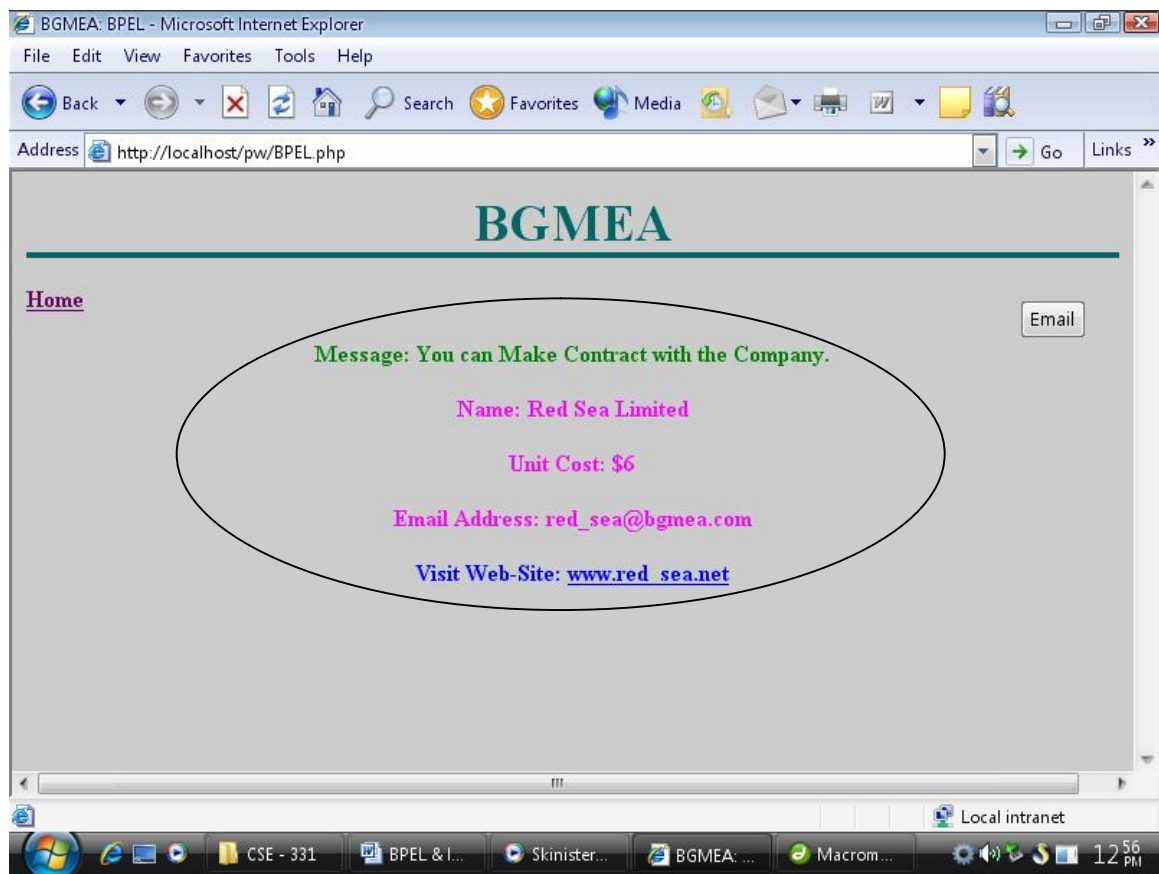

Figure 20

On success, that is, from the number of selected companies or company [if user has interest only on a single company] user will get a message which company can take the order when there are multiple companies involved. For a single company it will just show whether it can take the order or not.

From here, there will be a link to that company or user either chooses the email button to email to that company.

8.1.2 Back-end

The total code is divided into some sub phases which we call function and inside a function there may reside some phases. From our point of view we are explaining how the code works. To make it more clear we will give each phase a name.

Part # 01

```
function index()
{
.....
    <blockquote>
        <p align="left">Select a Category

        </p>
    </blockquote>
.....
}
```

Figure 21

This portion of code is for select option that a user will see when s/he will browse the page from BGMEA.

Part # 02

```

Function process()
{
.....
foreach ($links as $key => $value)
{
    $result01 = mysql_query("SELECT * FROM category WHERE Link
    = '$value'");
    while($row01 = mysql_fetch_array($result01))
        $db_info[] = $row01["Database"].".xml";
}
.....
// inside it there is another function
.....
}

```

Figure 23

This portion of code is for processing XML file.

Part # 04

```

function XmlStartElement($Parser, $Name, $Attrs)
{
.....
if($Name == "REG_NUM")
    $IsRightTag1 = true;
.....
}
function XmlEndElement($Parser, $Name)
{
.....
if($Name == "REG_NUM")
    $IsRightTag1 = false;
.....
}
function XmlTextData($Parser, $Data)
{
.....
if($IsRightTag1)
    $ReturnValue1 = $Data;
.....
}

```

Figure 24

This portion of code will parse XML file and retrieve information.

Part # 05

```
.....  
foreach ($db_info as $key => $value)  
{  
    $XmlParser = xml_parser_create();  
    xml_set_element_handler($XmlParser, "XmlStartElement",  
        "XmlEndElement");  
    xml_set_character_data_handler($XmlParser, "XmlTextData");  
  
    $strXML = implode("",file($value));          /* TAKING EACH XML  
    FILE */  
    xml_parse($XmlParser, $strXML, true);  
    xml_parser_free($XmlParser);  
  
    $combine_detail[] =  
    $ReturnValue1."|".$ReturnValue2."|".$ReturnValue3."|".$ReturnValu  
    e4."|".$ReturnValue5;          /* FORMATTING DATA */  
    $iter++;  
}  
.....
```

Figure 25

This portion is for when a buyer selects more than one company.

Part # 06

```

.....
$new_supply_con = mktime(0, 0, 0, $mm, $dd, $yyyy);
$today_con = mktime(0, 0, 0, $sys_mm, $sys_dd, $sys_yyyy);
$buf_diff = ($new_supply_con - $today_con) / ((60*60)*24);
if($iter == 1)
{
.....
list($sparse_reg, $sparse_ucost, $com_dmy, $sparse_fworker,
    $sparse_tworker) = split('[|]', $combine_detail[$iter]);
$sparse_day = substr($com_dmy, 0, 2);
.....
$sparse_day = (int) $sparse_day;
.....
$per_worker_cap = $capacity_day / $sparse_tworker;
$calc01 = ($per_worker_cap * $sparse_tworker) * $buf_diff;
.....

```

Figure 26

Here we just find out remaining date and per unit capacity in case of a person.

Part # 07

```

.....
if($calc01 < $quantity)
    // Sorry can't take the order
else
{
.....
    if($calc02 > 0)
        // Employed worker become free and join new task
    else
        // Don't get other worker
    if($calc03 < $quantity)
        // Can't complete the order
    else
        // Complete the task
.....
}
.....

```

Figure 27

Here actually we print whatever decision made by the system after analyzing the fact.

Part # 08

```

if($flag_c == -$iter)
  // No company can take the order
else
{
  for($i = 0; $i < $iter; $i++)
  {
    if($flag[$i] == "true")
    {
      $calc03 = ($buf_diff * ($parse_fworker[$i] *
$per_worker_cap[$i])) + $comp_add_worker[$i];
      if($click > 0)
      {
        if($dec_parse_ucost[$i] > $dec_parse_ucost[$i-1])
        {
          $temp_reg = $parse_reg[$i-1];
          $temp_cost = $dec_parse_ucost[$i-1];
        }
        else
        {
          $temp_reg = $parse_reg[$i];
          $temp_cost = $dec_parse_ucost[$i];
        }
      }
      $click++;
    }
  }
}

```

Figure 28

When there are more than one company involved we just find out the optimal one for the buyer.
